143A: Principles of Operating Systems

Lecture 4: Linking and Loading (Basic architecture of a program)

Anton Burtsev
October, 2018

What is a program?

- What parts do we need to run code?

Parts needed to run a program

- Code itself
  - By convention it's called text
- Stack
  - To call functions
- Space for variables
  - Ok... this is a bit tricky

What types of variables do you know?

What types of variables do you know?

- Global variables
  - Initialized → data section
  - Uninitalized → BSS
- Local variables
  - Stack
- Dynamic variables
  - Heap

Space for variables (3 types)

- Global variables

```
1. #include <stdio.h>
2.
3. char hello[] = "Hello";
4. int main(int ac, char **av)
5. {
6.     static char world[] = "world!";
7.     printf("%s %s\n", hello, world);
8.     return 0;
9. }
```

- Allocated in the data section
  - It is split in initialized (non-zero), and non-initialized (zero)
  - As well as read/write, and read only data section

Space for variables (3 types)

- Local variables

```
1. #include <stdio.h>
2.
3. char hello[] = "Hello";
4. int main(int ac, char **av)
5. {
6.     //static char world[] = "world!";
7.     char world[] = "world!";
8.     printf("%s %s\n", hello, world);
9.     return 0;
10.}
```

- Allocated on the stack
  - Remember calling conventions?

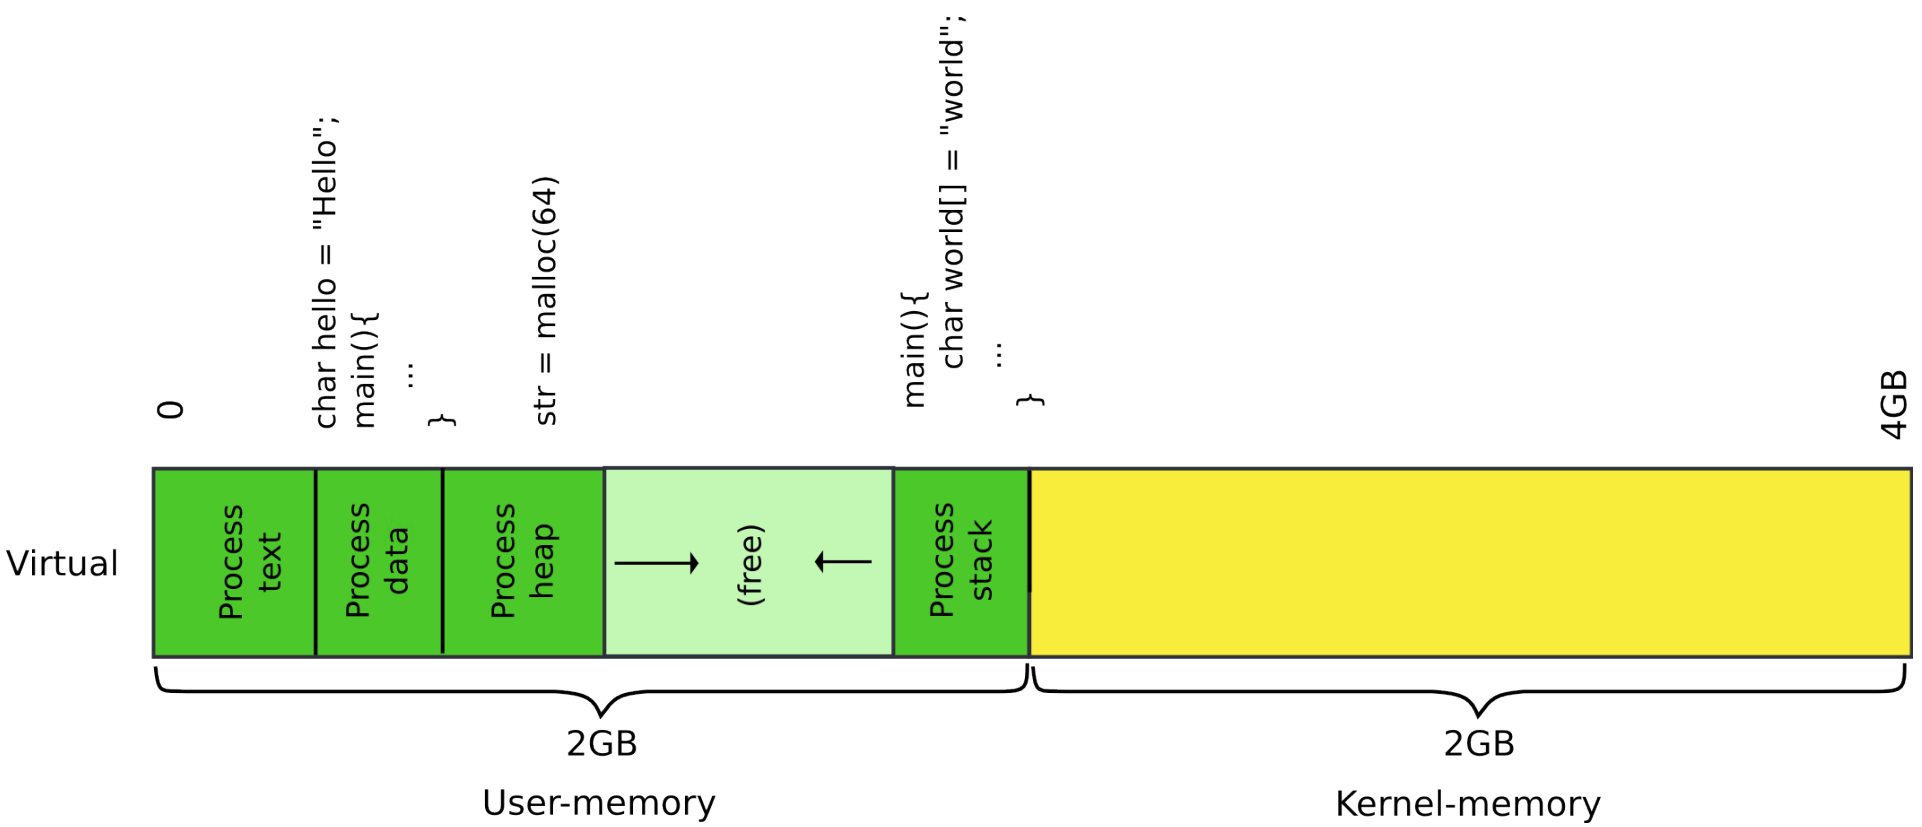
Space for variables (3 types)

- Local variables

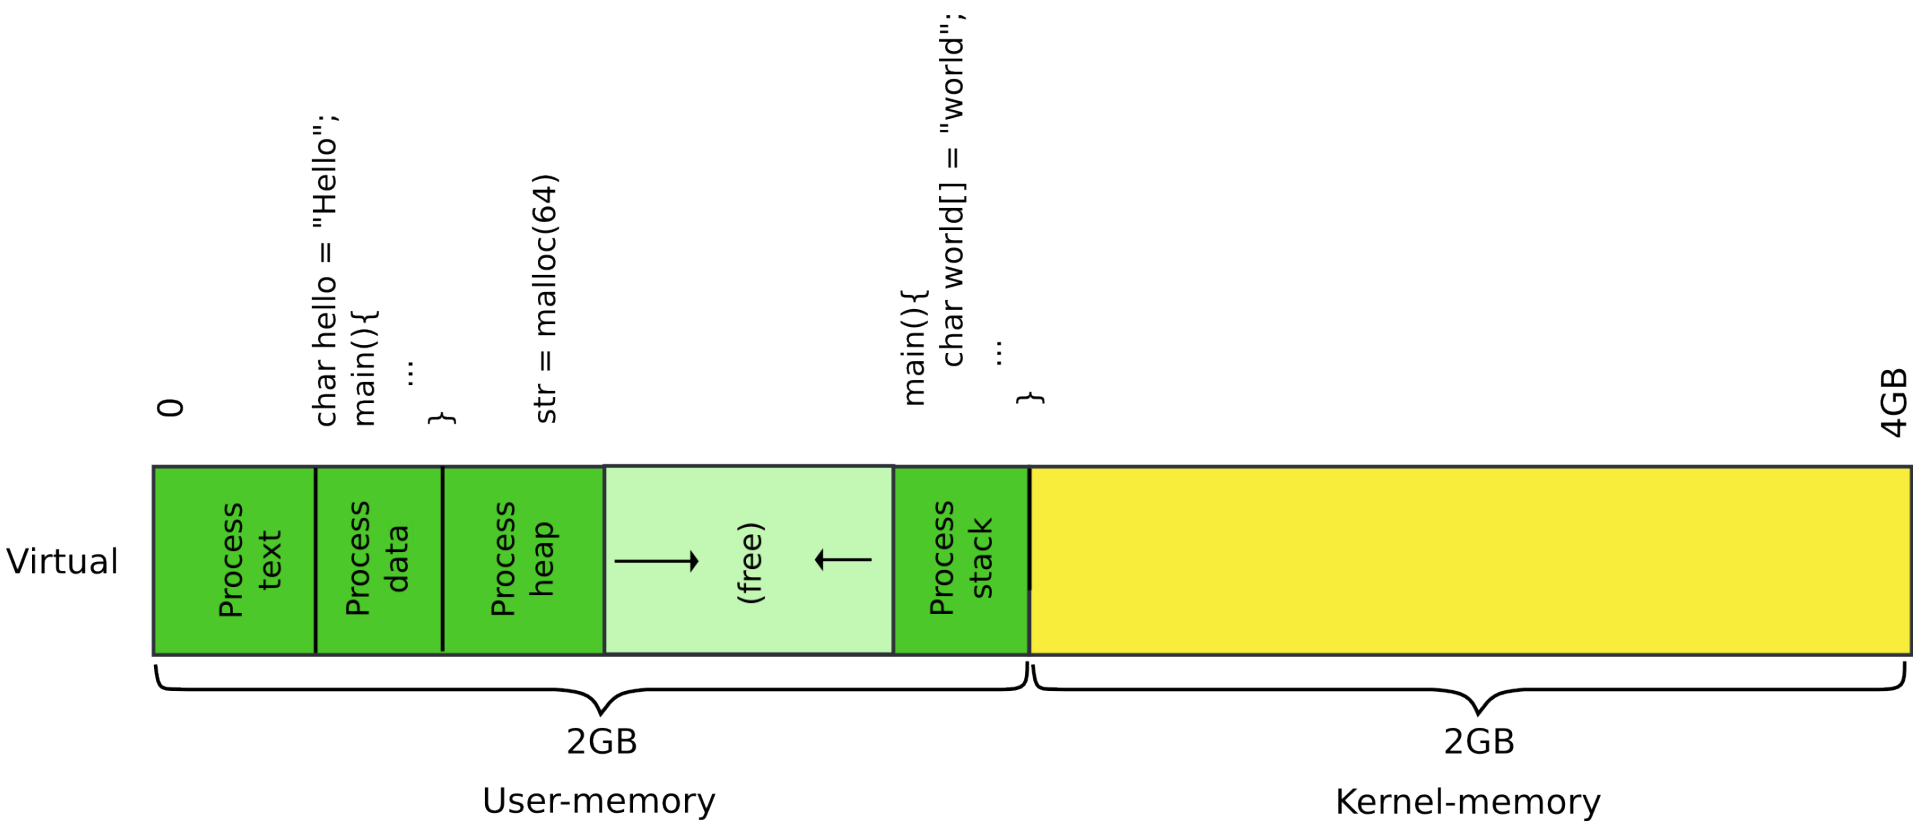
```
1. #include <stdio.h>
2. #include <string.h>
3. #include <stdlib.h>
4.
5. char hello[] = "Hello";
6. int main(int ac, char **av)
7. {
8.     char world[] = "world!";
9.     char *str = malloc(64);
10.    memcpy(str, "beautiful", 64);
11.    printf("%s %s %s\n", hello, str, world);
12.    return 0;
13.}
```

- Allocated on the heap
  - Special area of memory provided by the OS from where malloc() can allocate memory

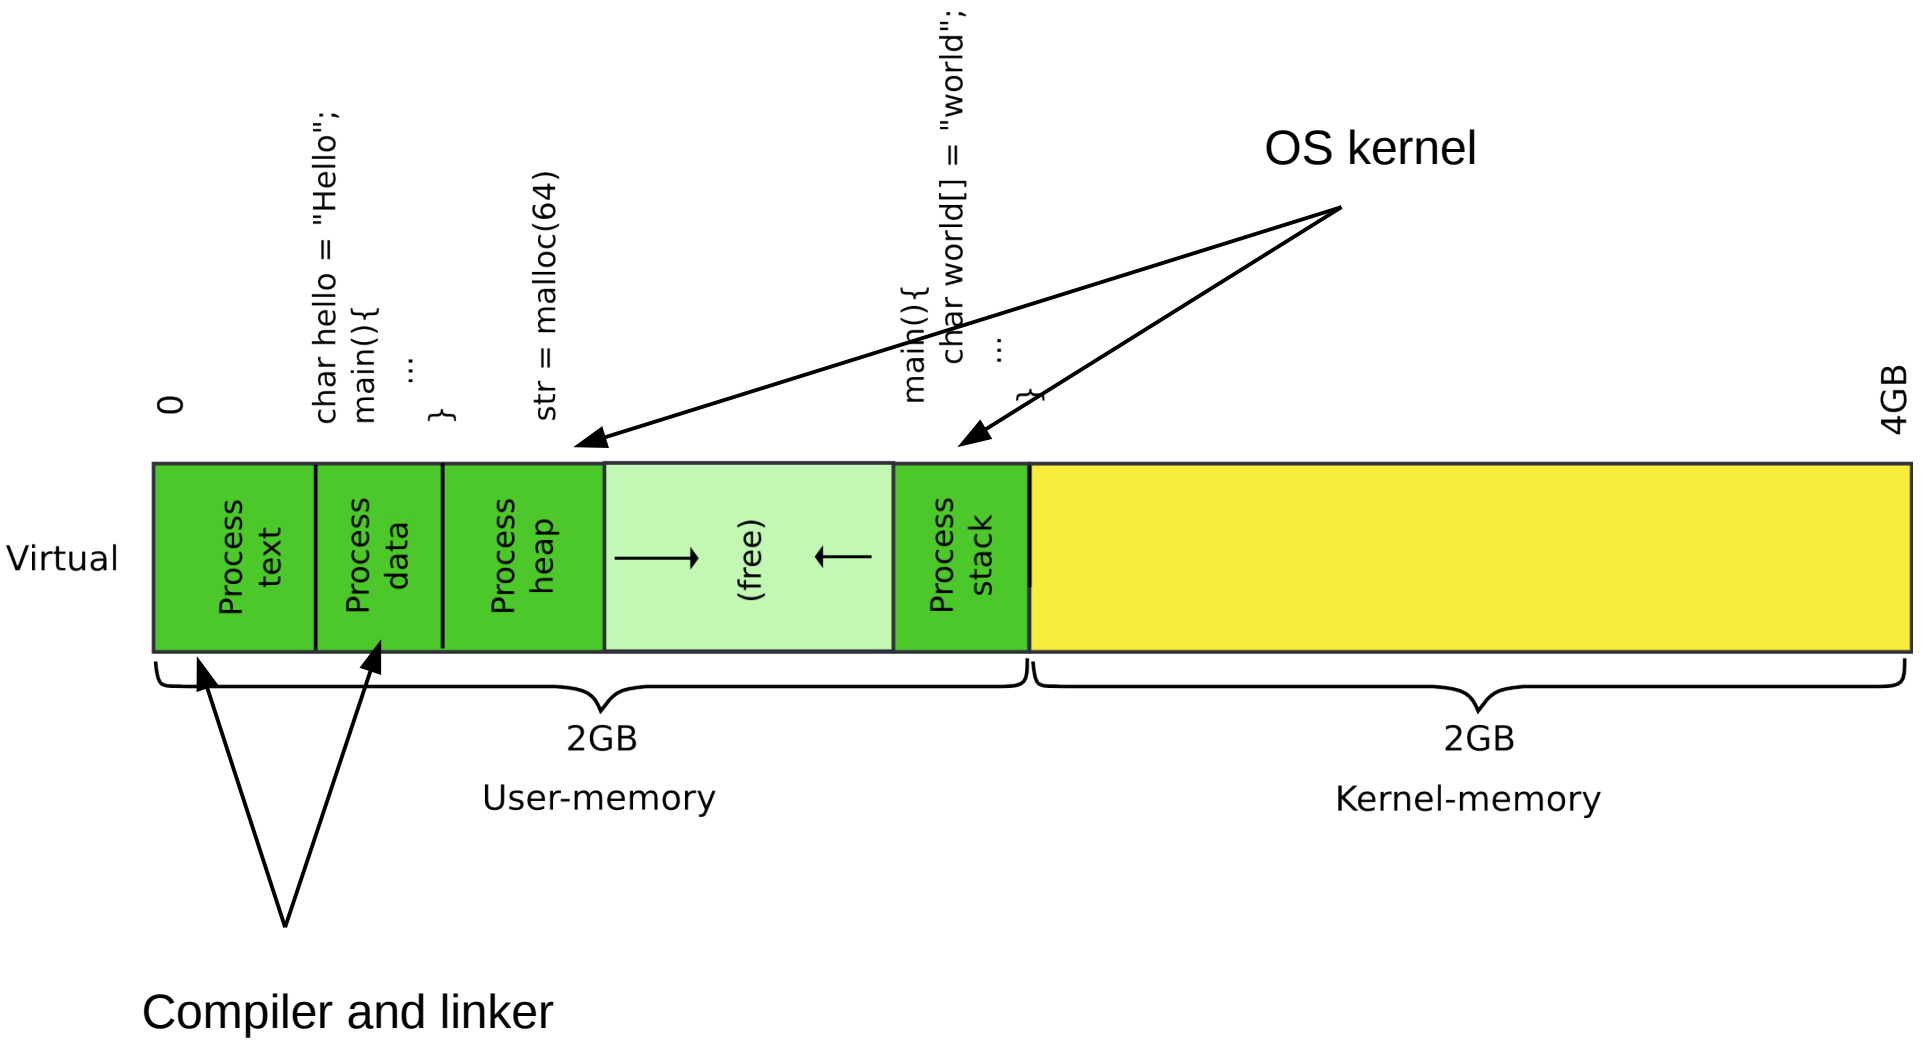
Memory layout of a process



Where do these areas come from?



Memory layout of a process



Example program

- Compute 5 + 6

```
#include <stdio.h>

int main(int ac, char **av)
{
    int a = 5, b = 6;
    return a + b;
}
```

- We build it like
  - I'm on 64 bit system, but want 32bit code, hence -m32

```
gcc -m32 hello-int.c
```

objdump -sd a.out

```
a.out:     file format elf32-i386

“Optimizing subroutines in assembly language” by Agner Fog:
https://www.agner.org/optimize/optimizing_assembly.pdf

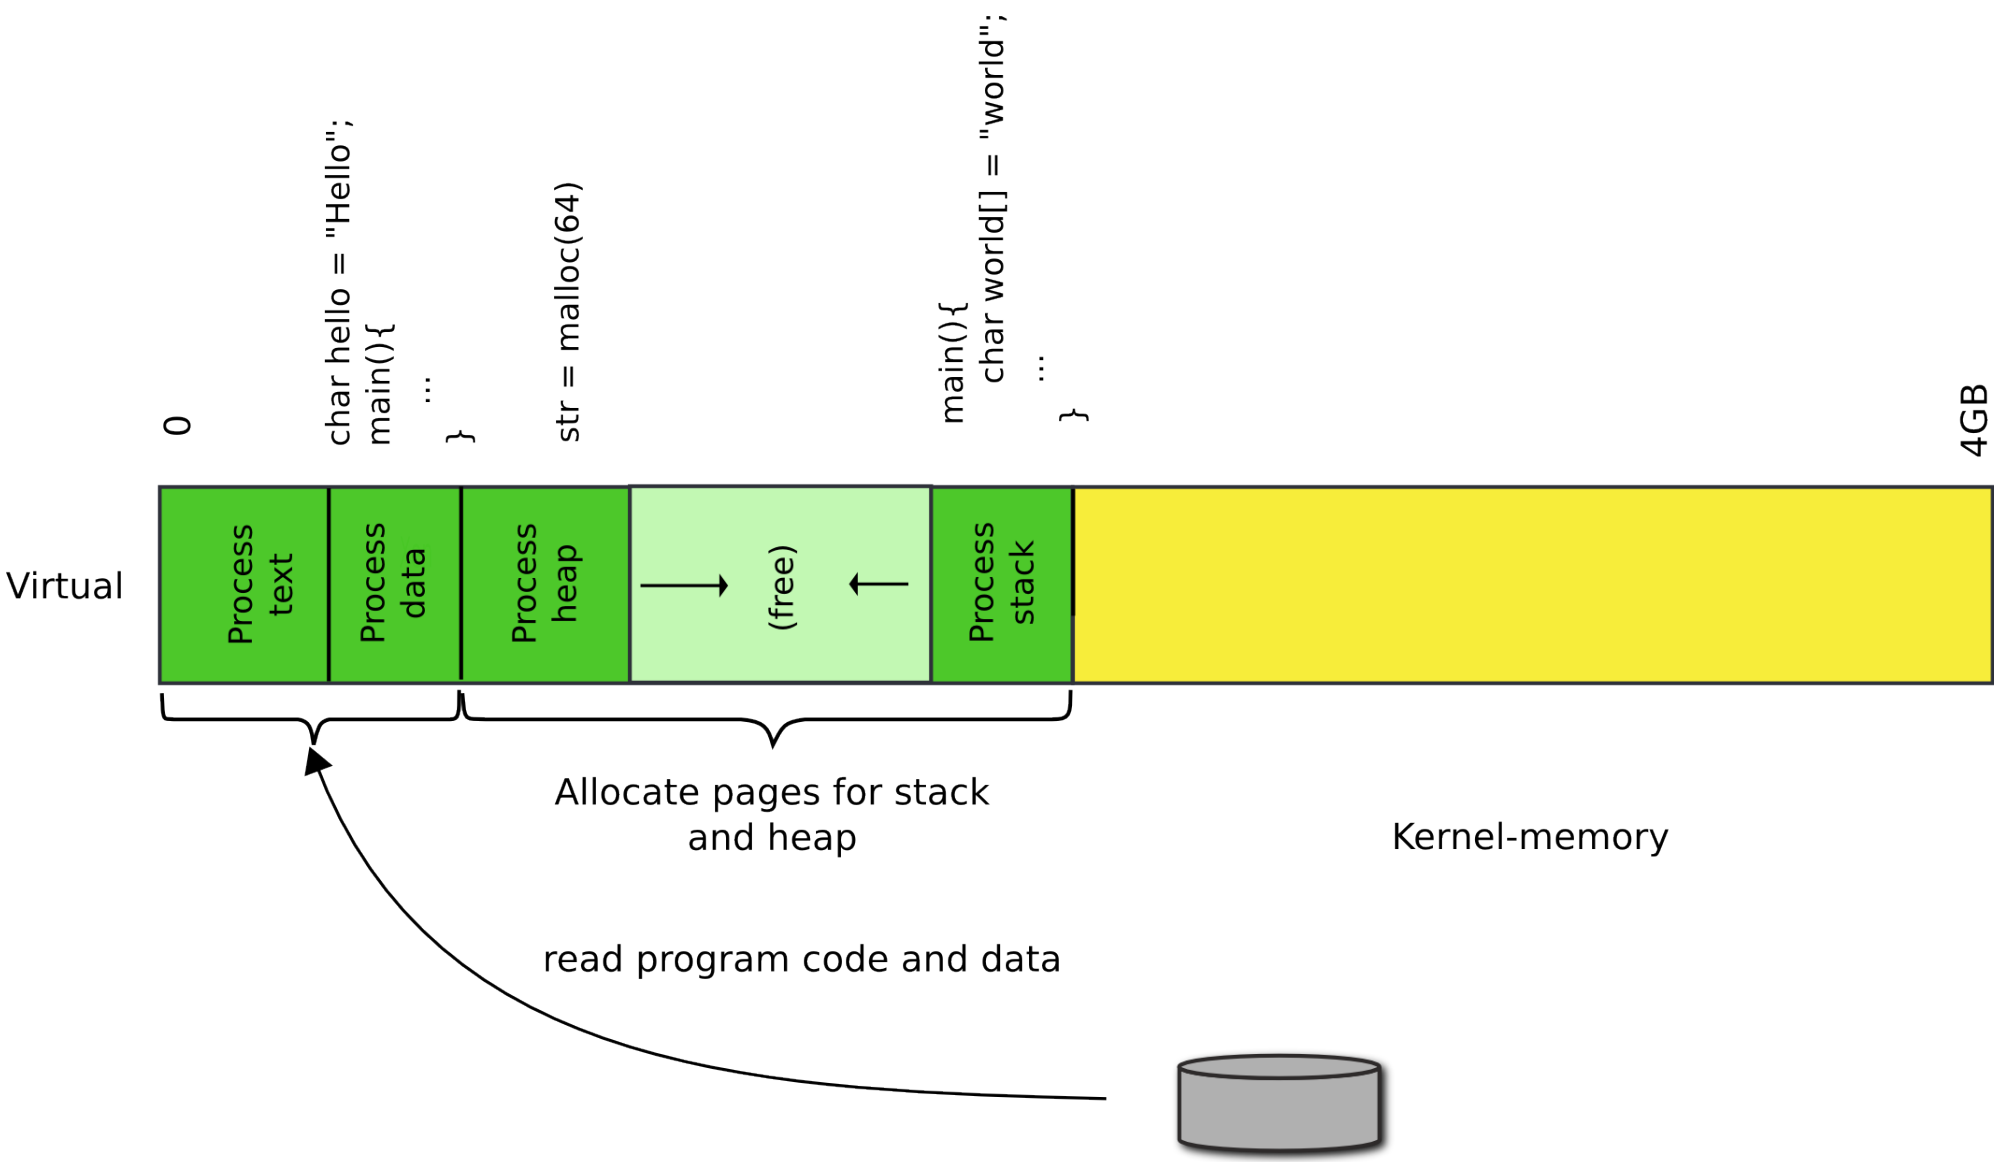
11.5 Alignment of code

Most microprocessors fetch code in aligned 16-byte or 32-byte blocks. If an important subroutine entry or jump label happens to be near the end of a 16-byte block then the microprocessor will only get a few useful bytes of code when fetching that block of code. It may have to fetch the next 16 bytes too before it can decode the first instructions after the label. This can be avoided by aligning important subroutine entries and loop entries by 16.

...

Aligning a subroutine entry is as simple as putting as many NOP 's as needed before the subroutine entry to make the address divisible by 8, 16, 32 or 64, as desired.

Load program in memory



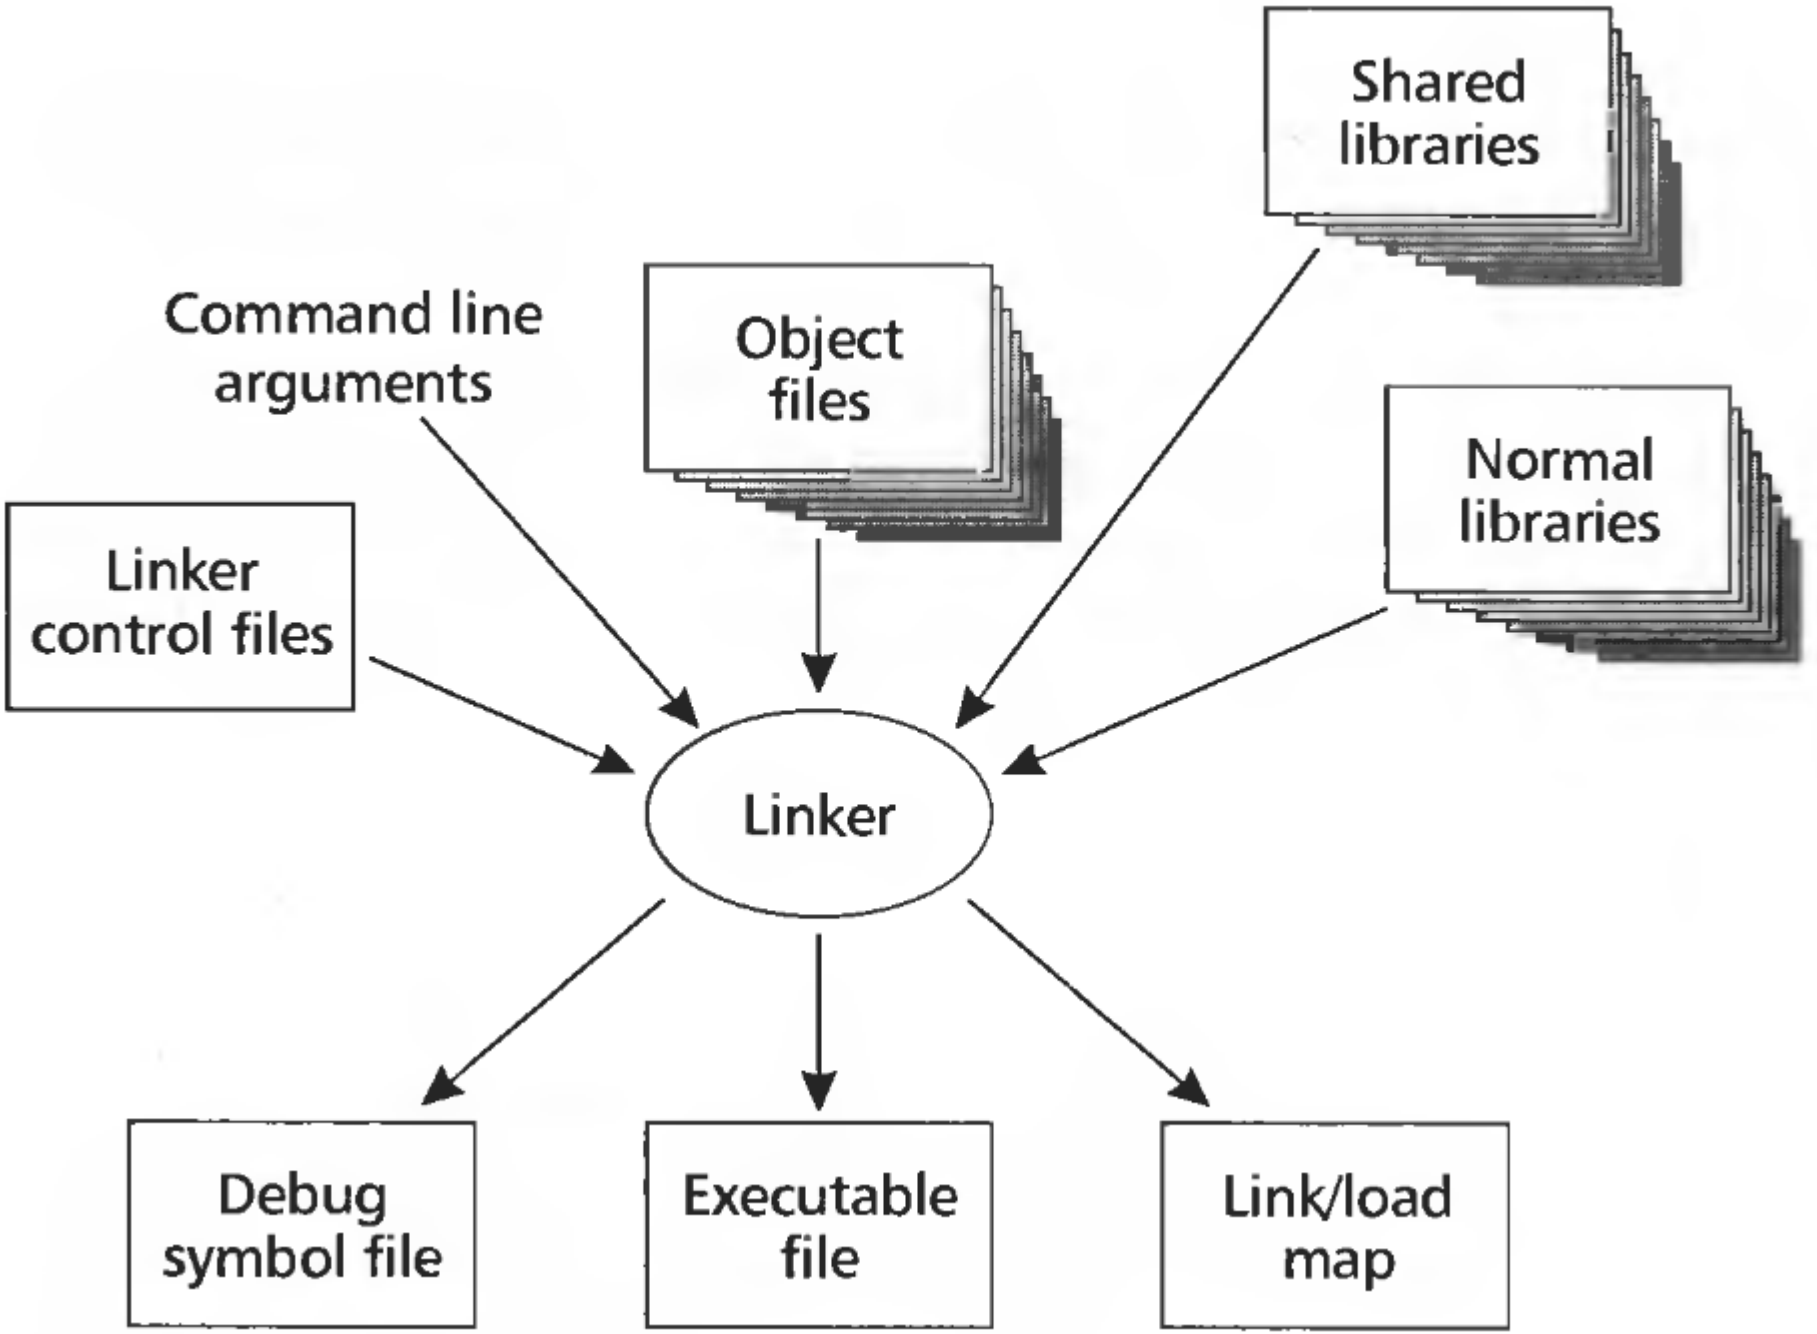
We however build programs from multiple files

Part of the xv6 Makefile

```
bootblock: bootasm.S bootmain.c
	$(CC) $(CFLAGS) -fno-pic -O -nostdinc -I. -c bootmain.c
	$(CC) $(CFLAGS) -fno-pic -nostdinc -I. -c bootasm.S
	$(LD) $(LDFLAGS) -N -e start -Ttext 0x7C00 -o bootblock.o bootasm.o bootmain.o
	$(OBJDUMP) -S bootblock.o > bootblock.asm
	$(OBJCOPY) -S -O binary -j .text bootblock.o bootblock
	./sign.pl bootblock
```

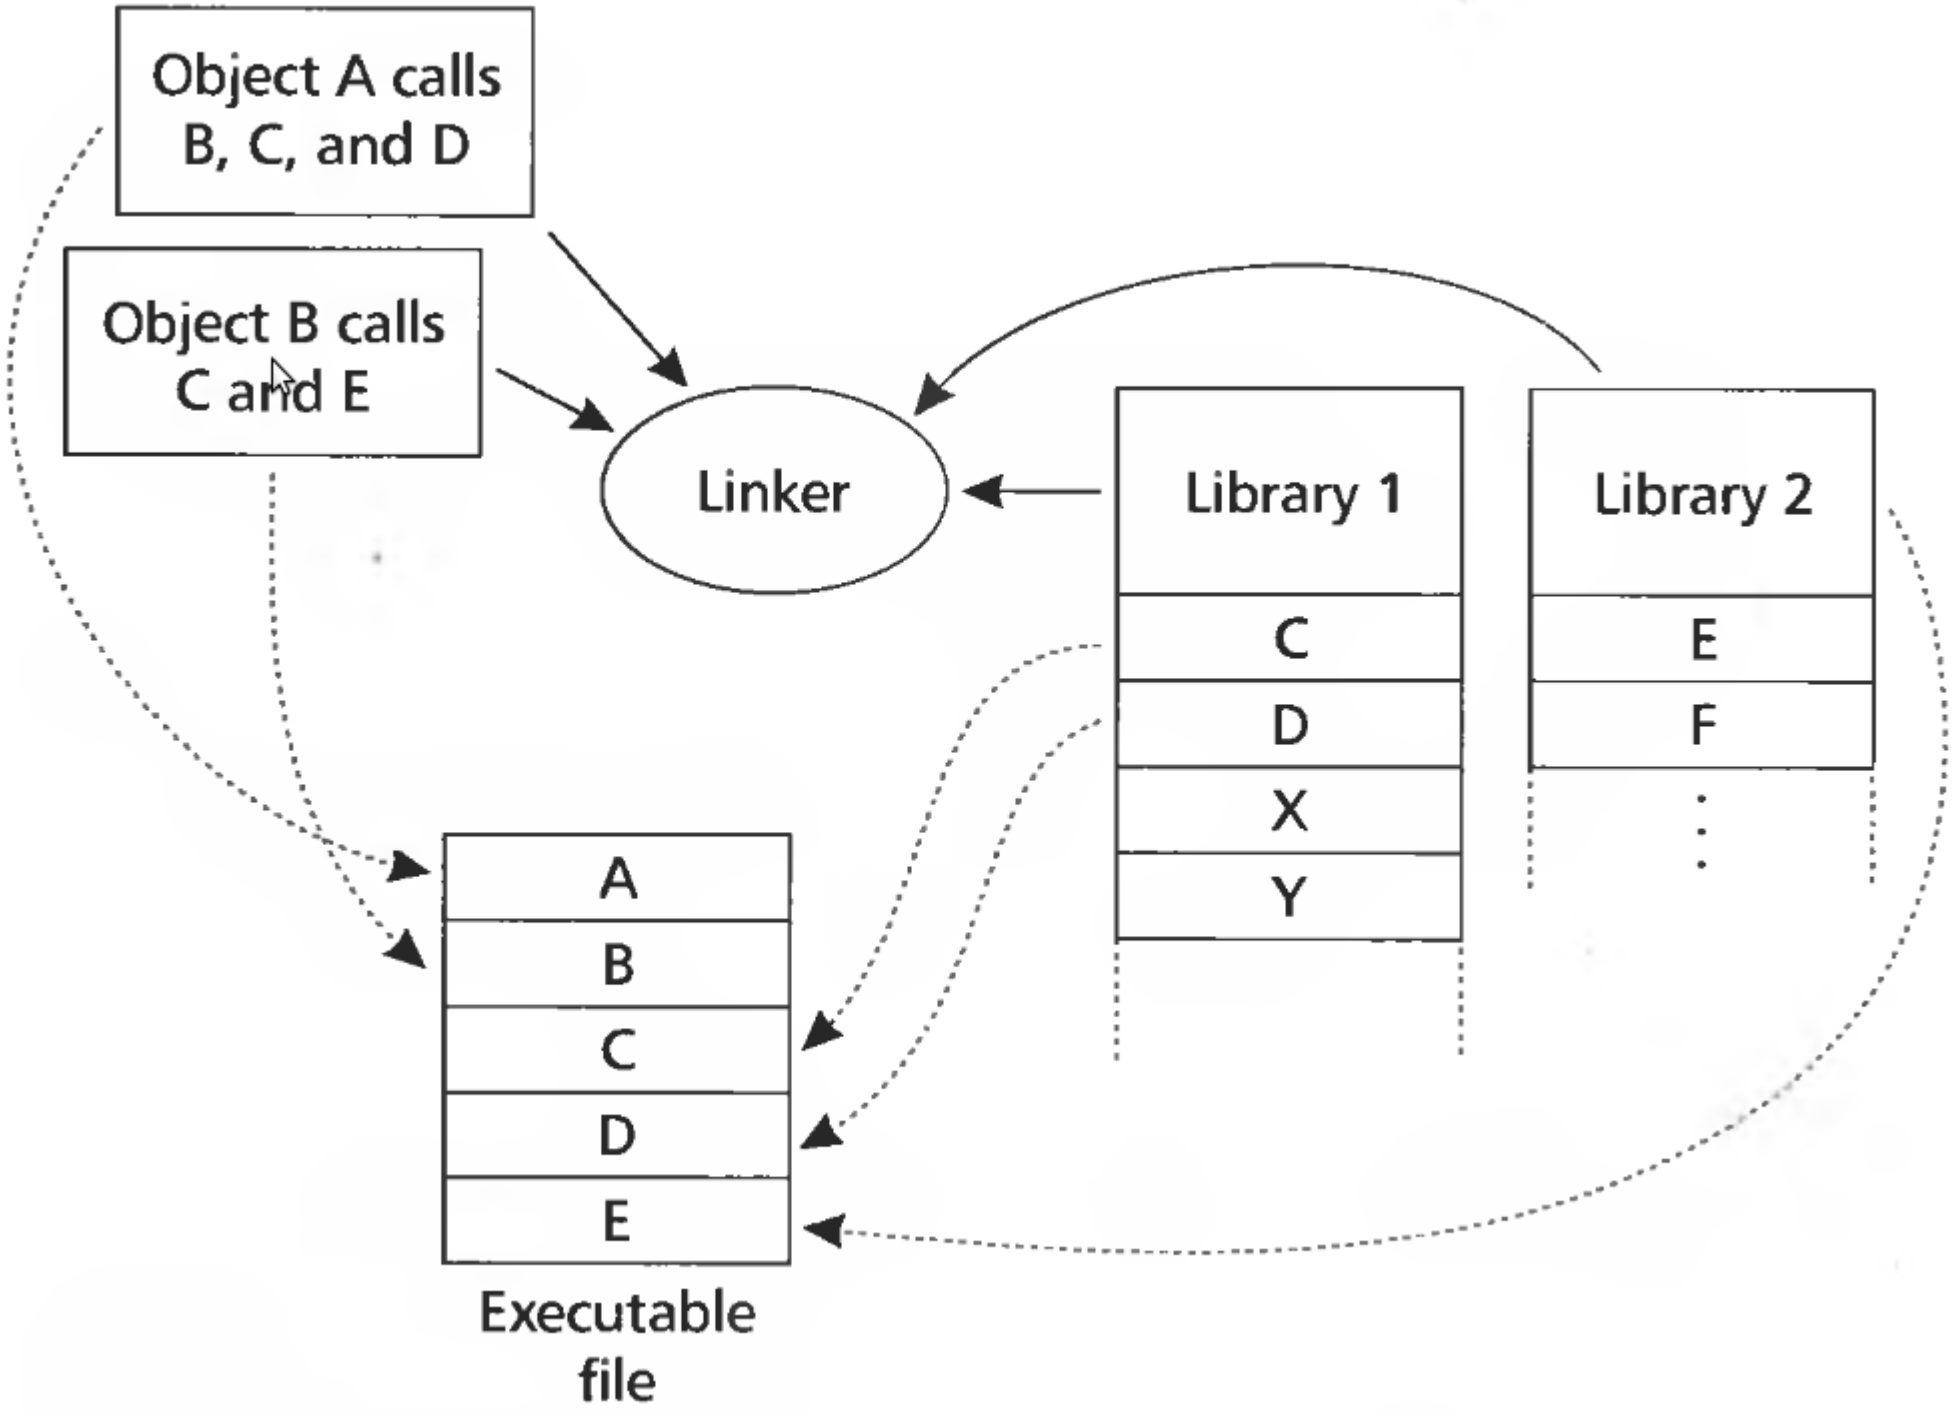
Linking and loading

- Linking
  - Combining multiple code modules into a single executable
  - E.g., use standard libraries in your own code
- Loading
  - Process of getting an executable running on the machine



Shared libraries
Command line arguments
Object files
Normal libraries
Linker control files
Linker
Debug symbol file
Executable file
Link/load map

- Input: object files (code modules)
- Each object file contains
  - A set of segments
    - Code
    - Data
  - A symbol table
    - Imported & exported symbols
- Output: executable file, library, etc.



Object A calls
B, C, and D
Object B calls
C and E
Linker
Library 1
C
D
X
Y
Library 2
E
F
A
B
C
D
E
Executable
file

Why linking?

Why linking?

- Modularity
  - Program can be written as a collection of modules
  - Can build libraries of common functions
- Efficiency
  - Code compilation
    - Change one source file, recompile it, and re-link the executable
  - Space efficiency
    - Share common code across executables
    - On disk and in memory

Two path process

- Path 1: scan input files
  - Identify boundaries of each segment
  - Collect all defined and undefined symbol information
  - Determine sizes and locations of each segment
- Path 2
  - Adjust memory addresses in code and data to reflect relocated segment addresses

Example

- Save a into b, e.g., b = a

```
mov a, %eax
mov %eax, b
```

- Generated code
  - a is defined in the same file at 0x1234, **b is imported**
  - Each instruction is 1 byte opcode + 4 bytes address

```
A1 34 12 00 00 mov a, %eax
A3 00 00 00 00 mov %eax, b
```

Example

- Save a into b, e.g., b = a

```
mov a, %eax
```

- 1 byte opcode

...nerated code

a is defined in the same file at 0x1234, **b is imported**

Each instruction is 1 byte opcode + 4 bytes address

```
A1 34 12 00 00 mov a, %eax
A3 00 00 00 00 mov %eax, b
```

Example

- Save a into b, e.g., b = a

```
mov a, %eax
```

- 4 byte address

Generated code

- a is defined in the same file at 0x1234, **b is imported**
- Each instruction is 1 byte opcode + 4 bytes address

```
A1 34 12 00 00 mov a, %eax
A3 00 00 00 00 mov %eax, b
```

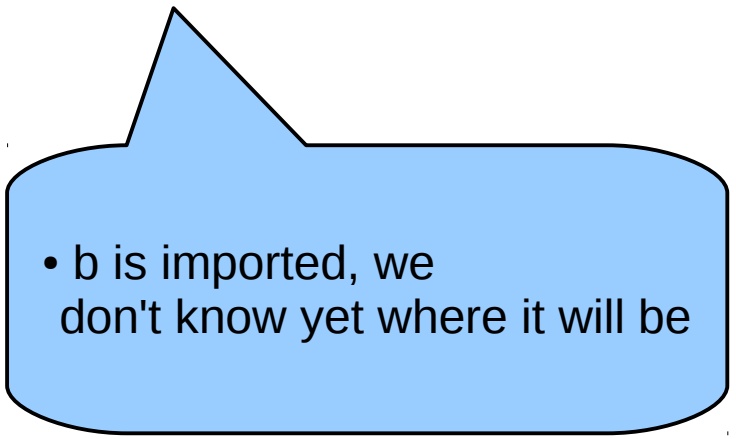
Example

- Save a into b, e.g., b = a

```
mov a, %eax
mov %eax, b
```

- Generated code
  - a is defined in the same file at 0x1234, **b is imported**
  - Each instruction is 1 byte opcode + 4 bytes address

```
A1 34 12 00 00 mov a, %eax
A3 00 00 00 00 mov %eax, b
```



Example

- Save a into b, e.g., b = a

```
mov a, %eax
mov %eax, b
```

- Generated code
  - a is defined in the same file at 0x1234, **b is imported**
  - Each instruction is 1 byte opcode + 4 bytes address

```
A1 34 12 00 00 mov a, %eax
A3 00 00 00 00 mov %eax, b
```

- Assume that a is relocated by 0x10000 bytes, and b is found at 0x9a12

```
A1 34 12 01 00 mov a,%eax
A3 12 9A 00 00 mov %eax,b
```

Example

- Save a into b, e.g., b = a

```
mov a, %eax
mov %eax, b
```

- Generated code
  - a is defined in the same file at 0x1234, **b is imported**
  - Each instruction is 1 byte opcode + 4 bytes address

```
A1 34 12 00 00 mov a, %eax
A3 00 00 00 00 mov %eax, b
```

- Assume that a is relocated by 0x10000 bytes, and b is found at 0x9a12

```
A1 34 12 01 00 mov a,%eax
A3 12 9A 00 00 mov %eax,b
```

More realistic example

- Source file m.c

```
1   extern void a(char *);
2   int main(int ac, char **av)
3   {
4     static char string[] = "Hello, world!\n";
5     a(string);
6   }
```

- Source file a.c

```
1   #include <unistd.h>
2   #include <string.h>
3   void a(char *s)
4   {
5     write(1, s, strlen(s));
6   }
```

More realistic example

- Source file m.c

```
1  extern void a(char *);
2  int main(int ac, char **av)
3  {
4    static char string[] = "Hello, world!\n";
5    a(string);
6  }
```

- Source file a.c

```
1  #include <unistd.h>
2  #include <string.h>
3  void a(char *s)
4  {
5    write(1, s, strlen(s));
6  }
```

More realistic example

- Source file m.c

```
1  extern void a(char *);
2  int main(int ac, char **av)
3  {
4    static char string[] = "Hello, world!\n";
5    a(string);
6  }
```

- Source file a.c

```
1  #include <unistd.h>
2  #include <string.h>
3  void a(char *s)
4  {
5    write(1, s, strlen(s));
6  }
```

More realistic example

```

```

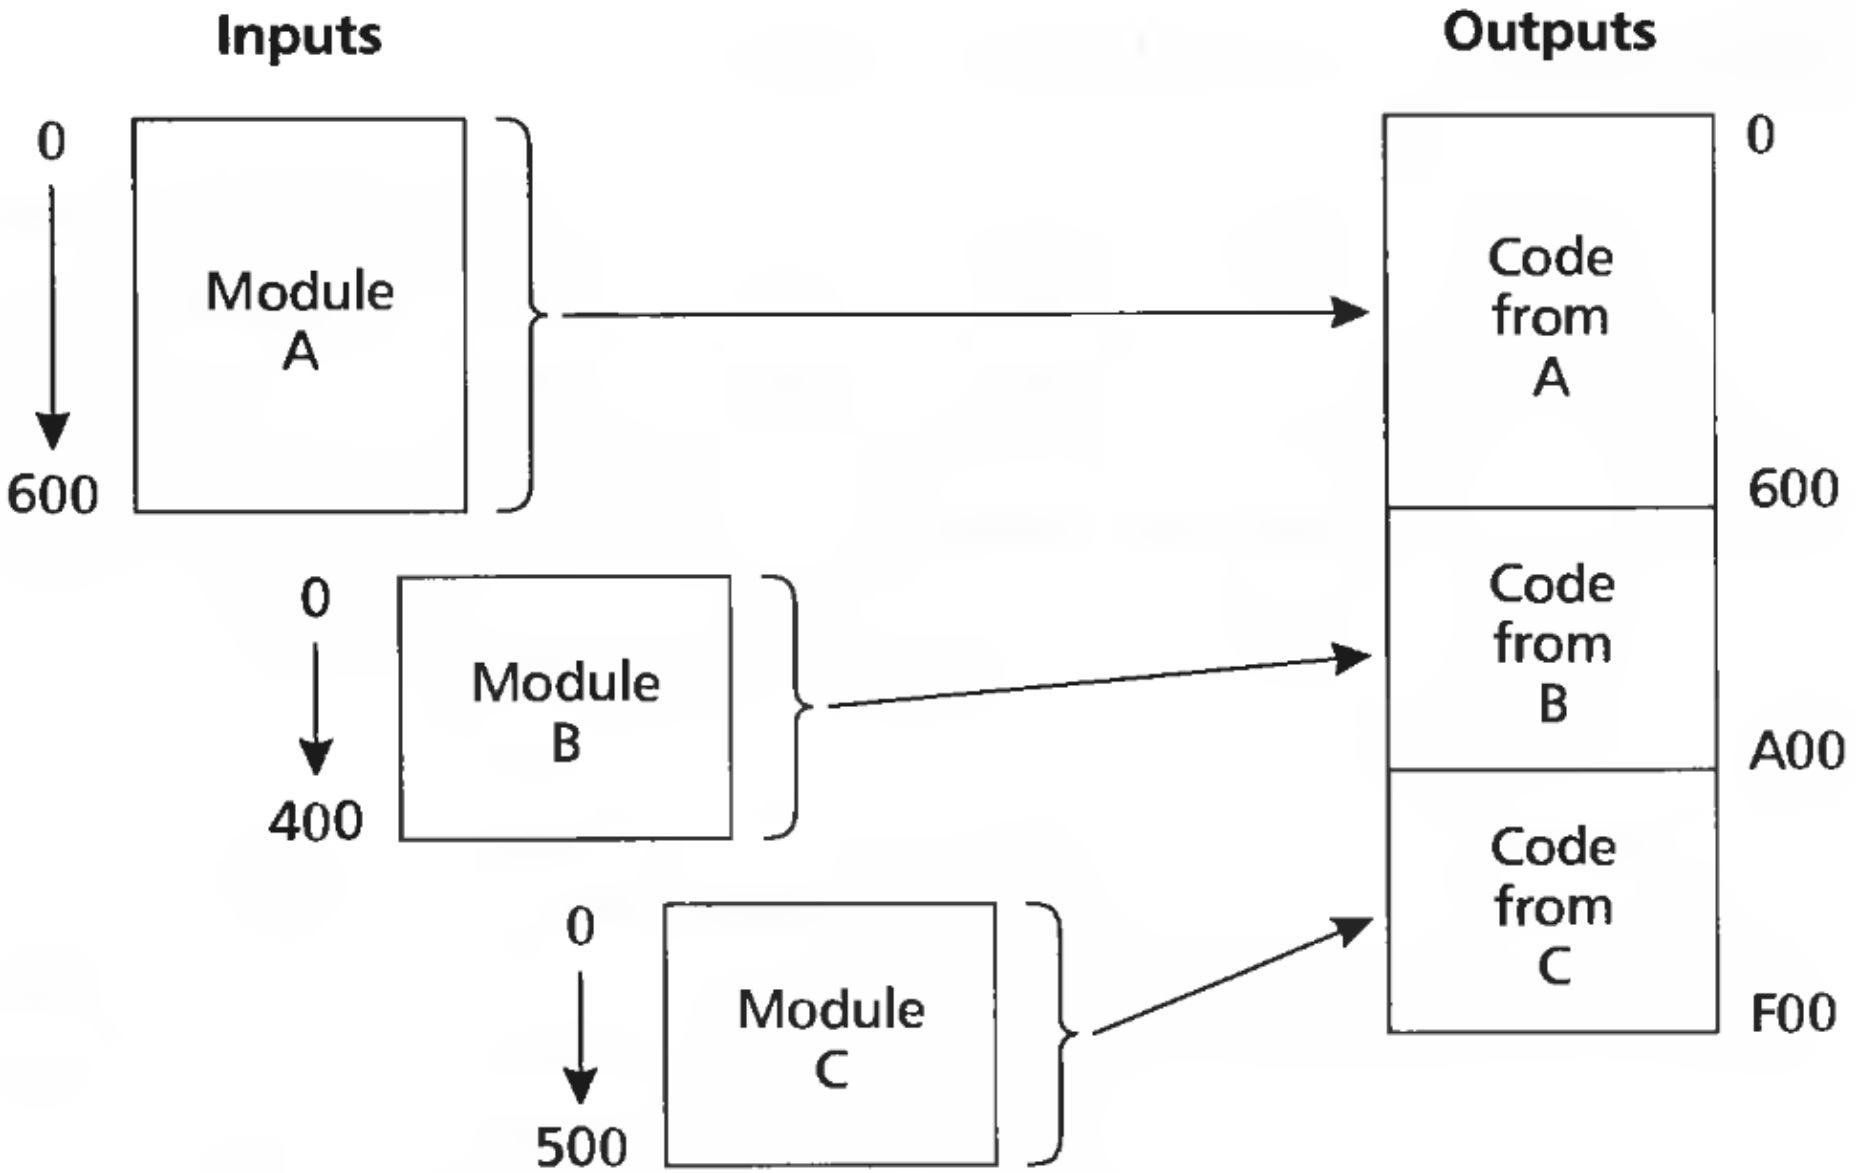
- Two relocation entries:
  - strlen()
  - write()

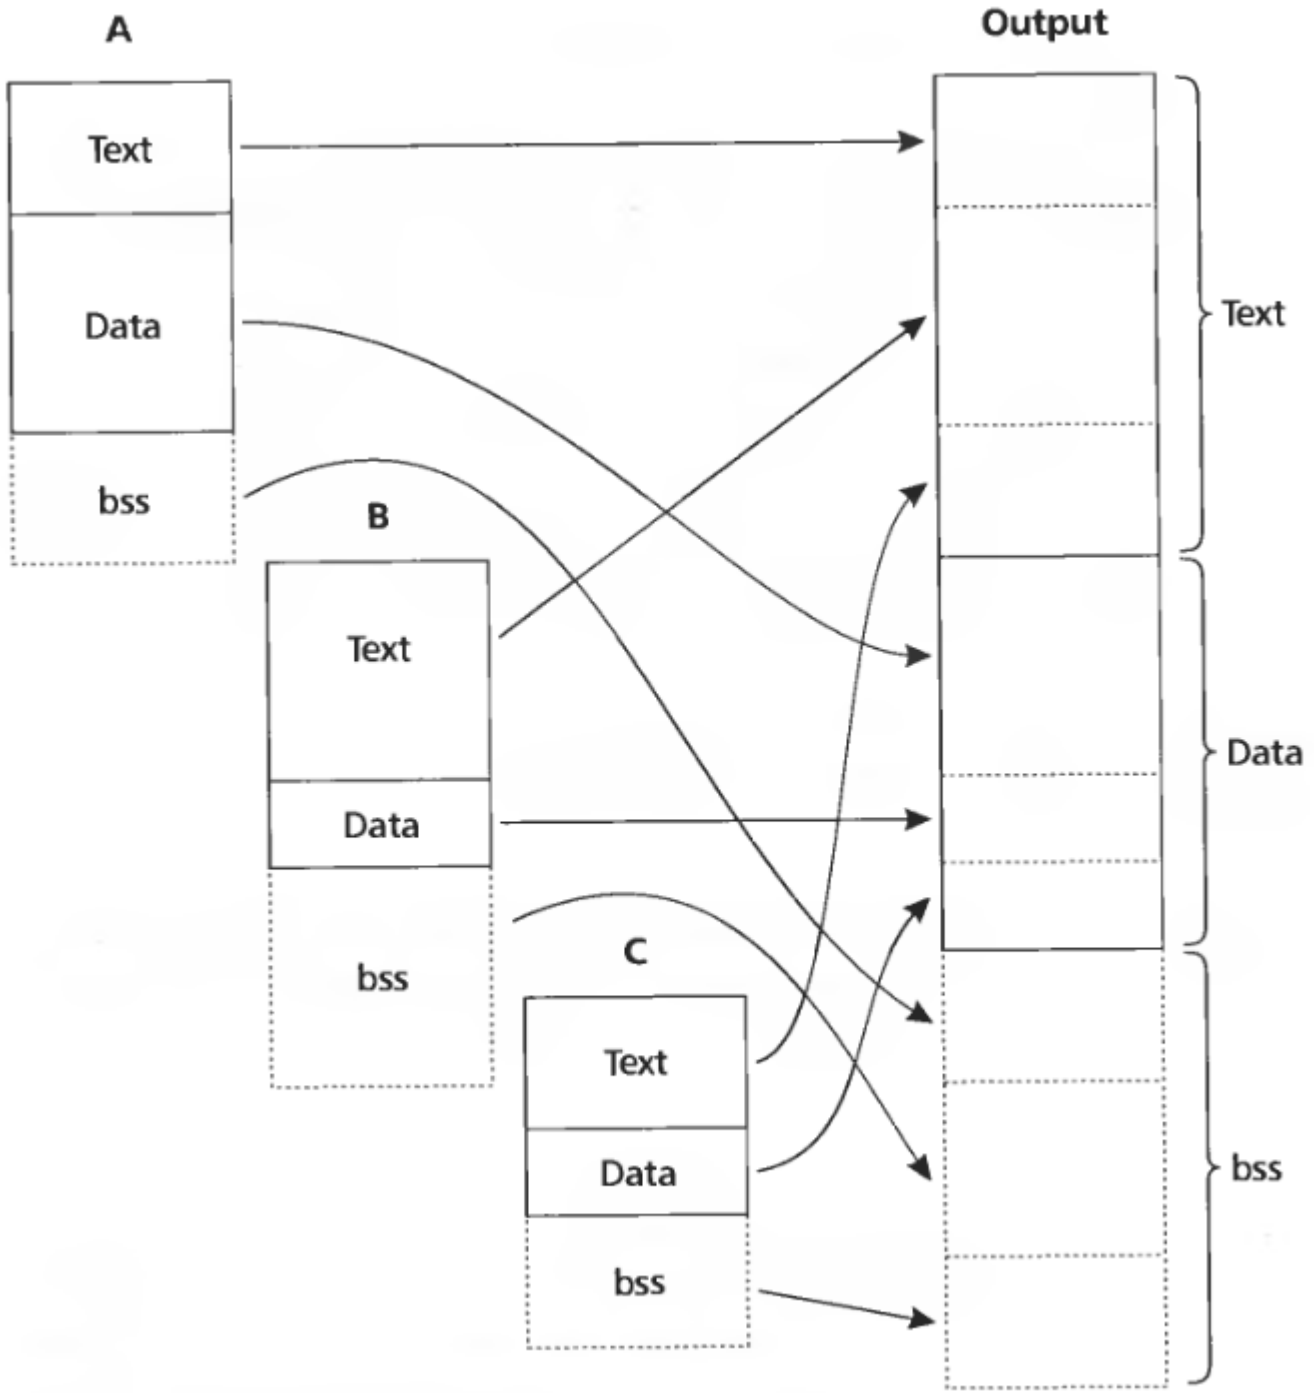
Producing an executable

- Combine corresponding segments from each object file
  - Combined text segment
  - Combined data segment
- Pad each segment to 4KB to match the page size

Multiple object files



Merging segments



```

```

Linked executable

Tasks involved

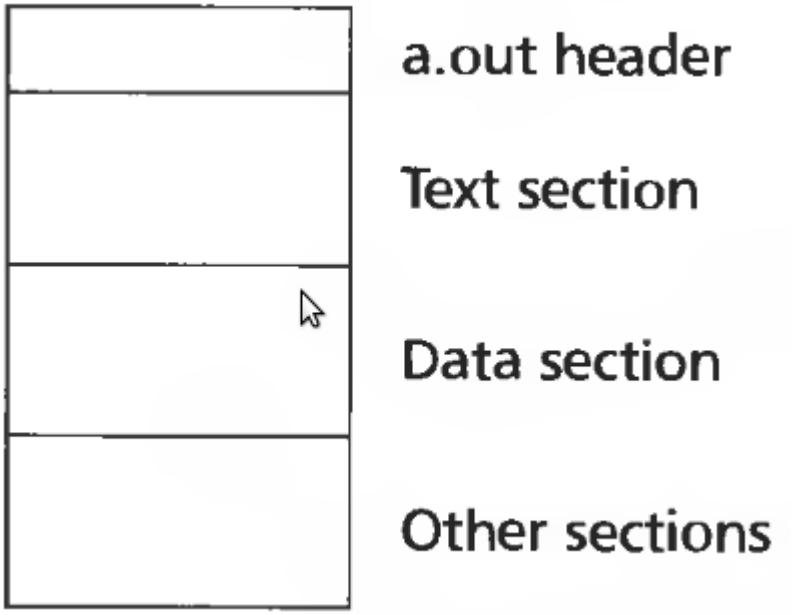
- Program loading
  - Copy a program from disk to memory so it is ready to run
    - Allocation of memory
    - Setting protection bits (e.g. read only)
- Relocation
  - Assign load address to each object file
  - Adjust the code
- Symbol resolution
  - Resolve symbols imported from other object files

Object files

Object files

- Conceptually: five kinds of information
  - Header: code size, name of the source file, creation date
  - Object code: binary instruction and data generated by the compiler
  - Relocation information: list of places in the object code that need to be patched
  - Symbols: global symbols defined by this module
    - Symbols to be imported from other modules
  - Debugging information: source file and file number information, local symbols, data structure description

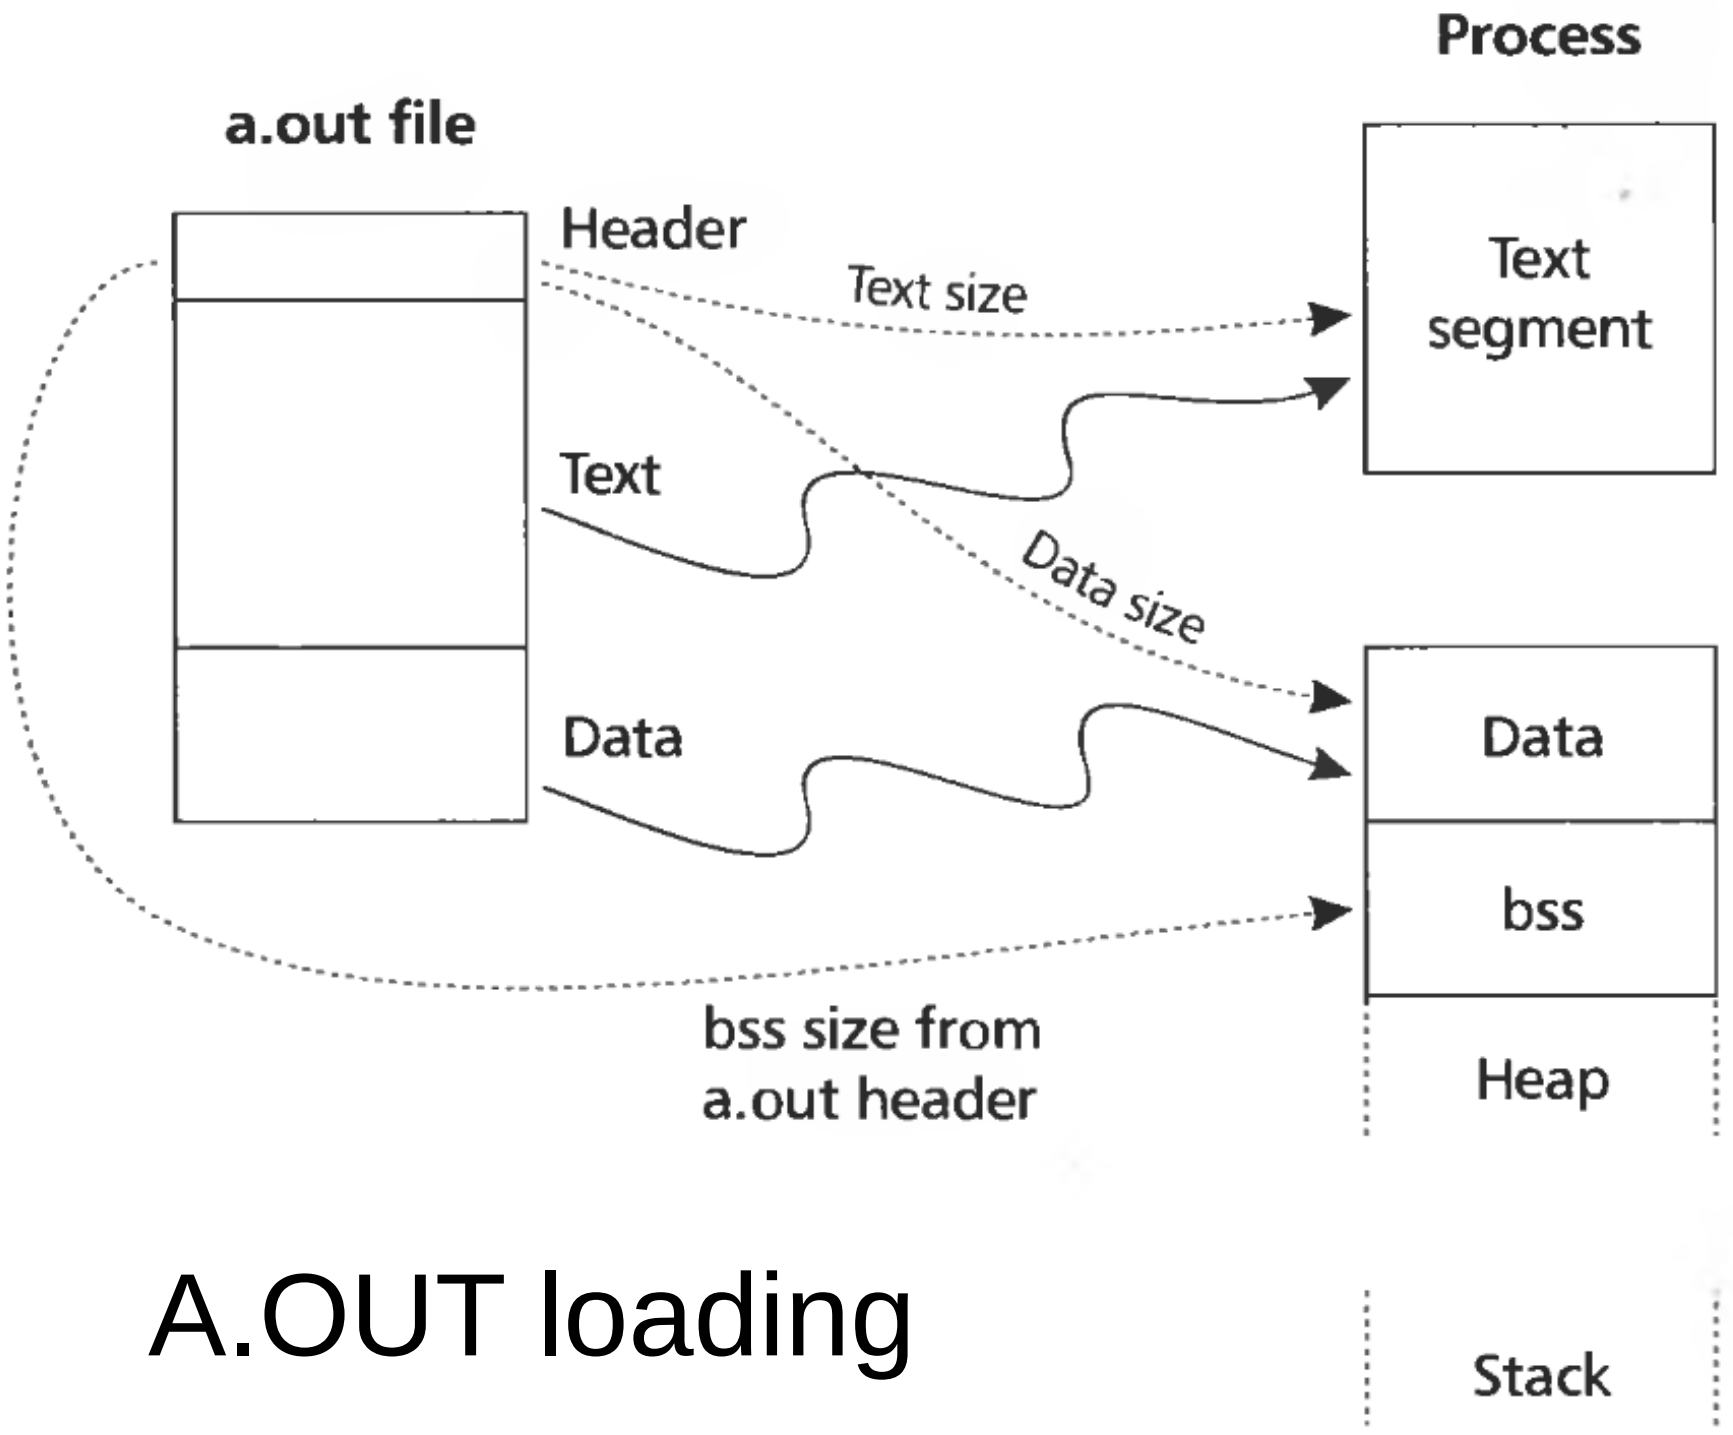
Example: UNIX A.OUT



- Small header
- Text section
  - Executable code
- Data section
  - Initial values for static data

- A.OUT header

```
int a_magic;  // magic number
int a_text;   // text segment size
int a_data;   // initialized data size
int a_bss;    // uninitialized data size
int a_syms;   // symbol table size
int a_entry;  // entry point
int a_trsize; // text relocation size
int a_drsize; // data relocation size
```



A.OUT loading

A.OUT loading

- Read the header to get segment sizes
- Check if there is a shareable code segment for this file
  - If not, create one,
  - Map into the address space,
  - Read segment from a file into the address space
- Create a private data segment
  - Large enough for data and BSS
  - Read data segment, zero out the BSS segment
- Create and map stack segment
  - Place arguments from the command line on the stack
- Jump to the entry point

Types of object files

- Relocatable object files (.o)
- Static libraries (.a)
- Shared libraries (.so)
- Executable files

- We looked at A.OUT, but Unix has a general format capable to hold all of these files

ELF

Elf header

- Magic number, type (.o, exec, .so), machine, byte ordering, etc.

Segment header table

- Page size, virtual addresses memory segments (sections), segment sizes.

`.text` section

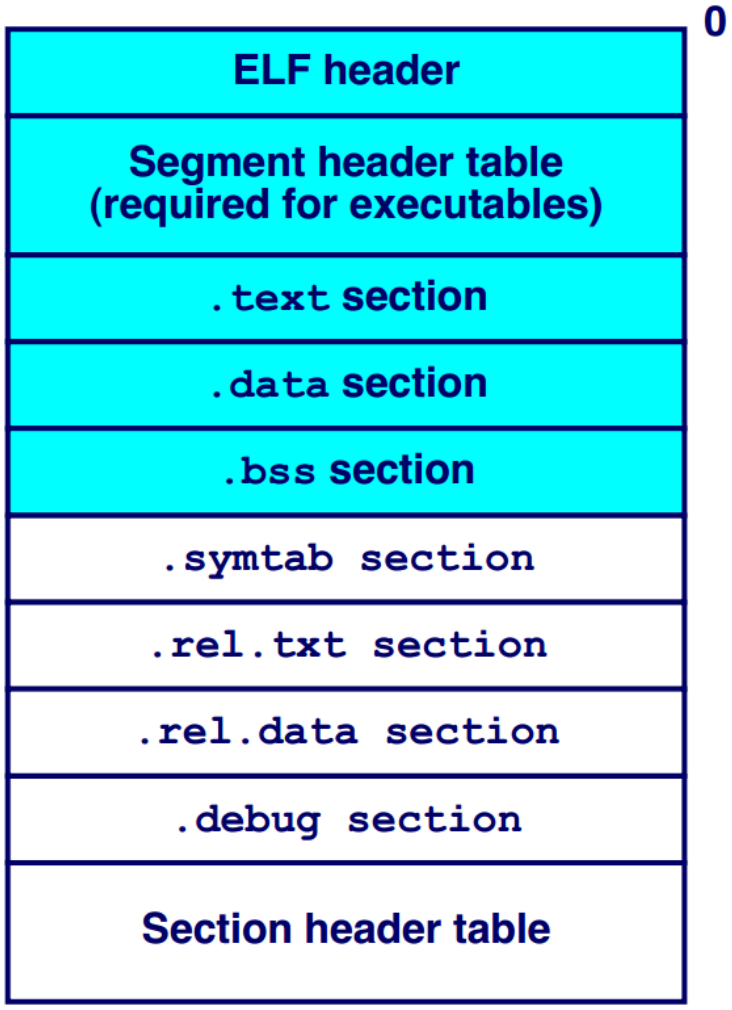
- Code

`.data` section

- Initialized global variables

`.bss` section

- Uninitialized global variables
- "Block Started by Symbol"
- "Better Save Space"
- Has section header but occupies no space



ELF (continued)

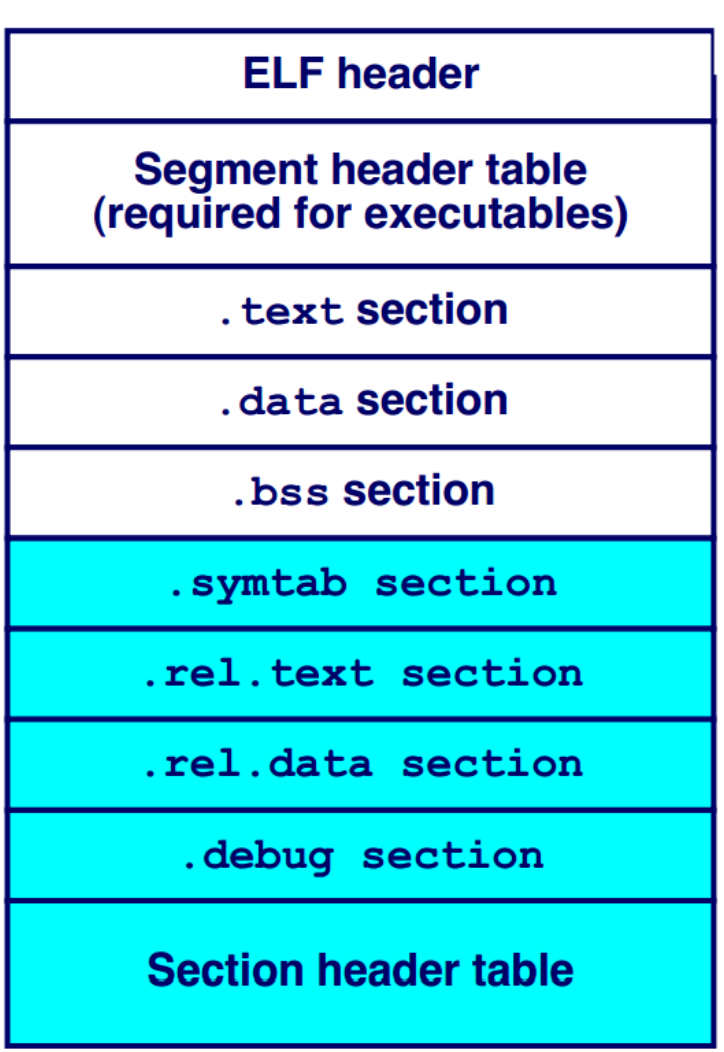
`.symtab` section
- Symbol table
- Procedure and static variable names
- Section names and locations

`.rel.text` section
- Relocation info for `.text` section
- Addresses of instructions that will need to be modified in the executable
- Instructions for modifying.

`.rel.data` section
- Relocation info for `.data` section
- Addresses of pointer data that will need to be modified in the merged executable

`.debug` section
- Info for symbolic debugging (`gcc -g`)

Section header table
- Offsets and sizes of each section



Initializers and finalizers

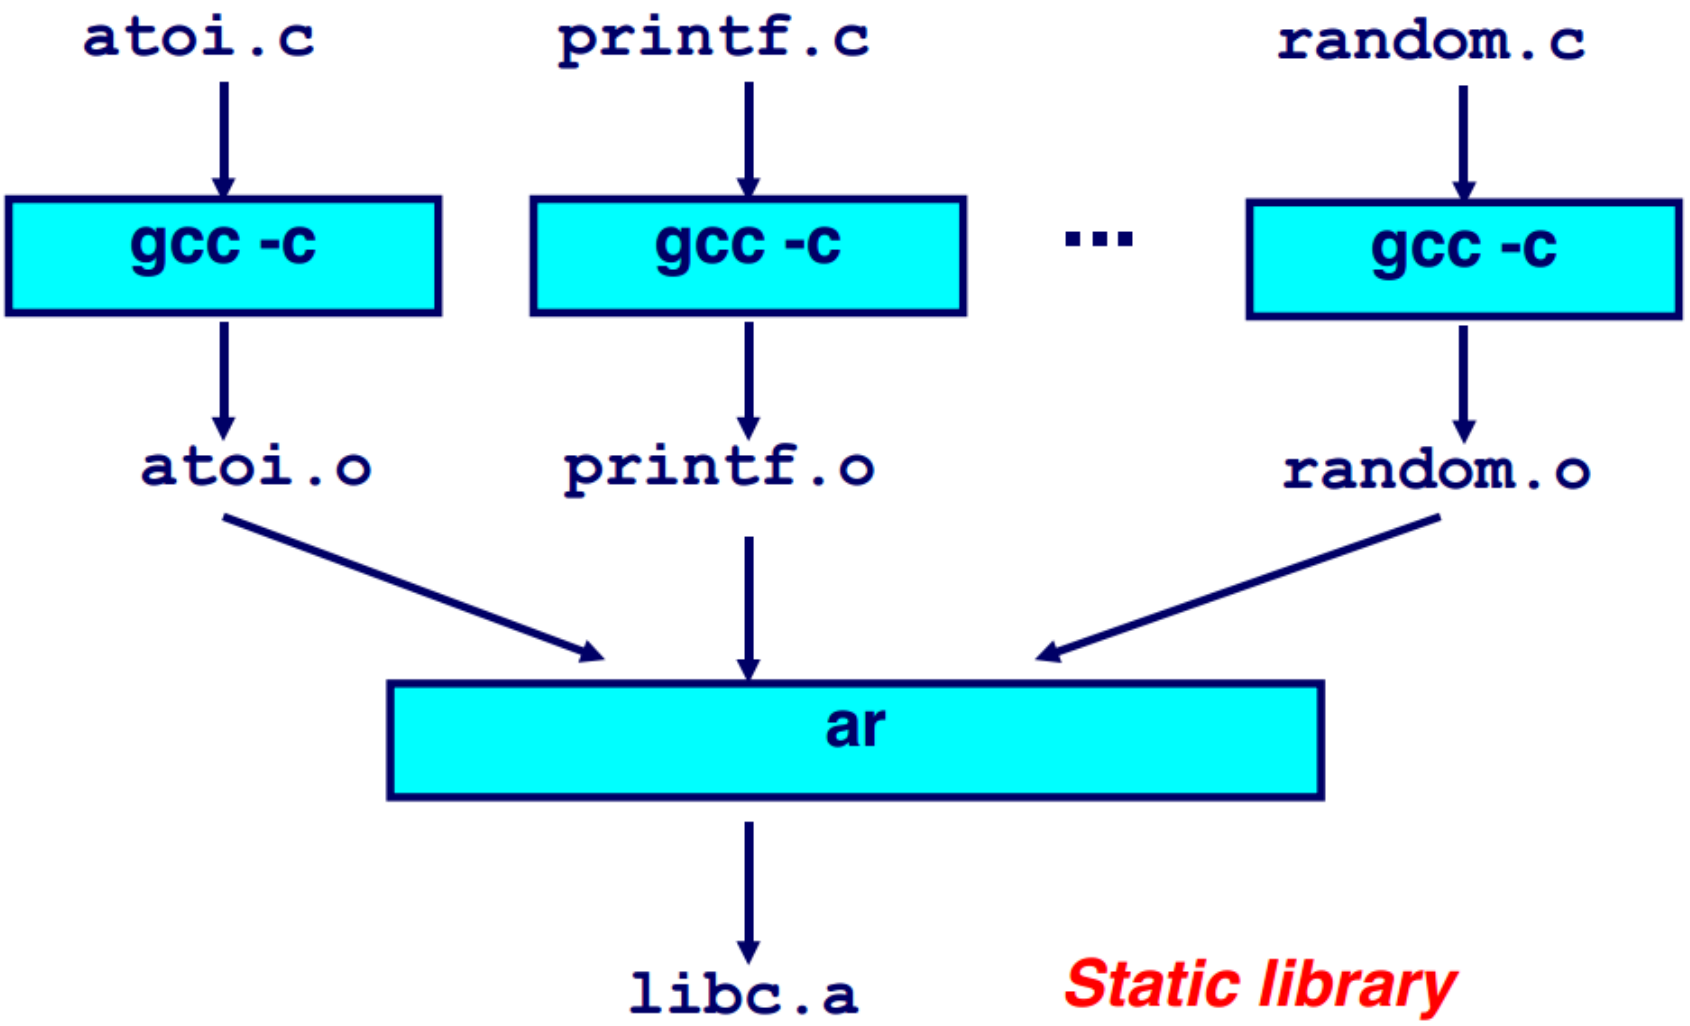
- C++ needs a segment for invoking constructors for static variables
  - List of pointers to startup routines
    - Startup code in every module is put into an anonymous startup routine
    - Put into a segment called .init
- Problem
  - Order matters
  - Ideally you should track dependencies
    - This is not done
  - Simple hack
    - System libraries go first (.init), then user (.ctor)

Static libraries

Libraries

- Conceptually a library is
  - Collection of object files
- UNIX uses an archive format
    - Remember the **ar** tool
  - Can support collections of any objects
  - Rarely used for anything instead of libraries

Creating a static library



Searching libraries

- First linker path needs resolve symbol names into function locations
- To improve the search library formats add a directory
  - Map names to member positions

Shared libraries
(.so or .dll)

Motivation

- 1000 programs in a typical UNIX system
- 1000 copies of printf

- **How big is `printf()` actually?**

Motivation

- Disk space
  - 2504 programs in /usr/bin on my Linux laptop
    - `ls /usr/bin | wc -l`
  - **`printf()` is a large function**
  - **Handles conversion of multiple types to strings**
    - **5-10K**
  - This means 10-25MB of disk can be wasted just on `printf()`
- Runtime memory costs are
  - 5-10K times the number of running programs
  - 250 programs running on my Linux laptop
    - `ps -aux | wc -l`
    - 1MB-2.5MB – huge number for most systems 15-20 years ago

Shared libraries

- Motivation
  - Share code of a library across all processes
    - E.g. libc is linked by all processes in the system
  - Code section should remain identical
    - To be shared read-only
  - What if library is loaded at different addresses?
    - Remember it needs to be relocated

Example: size of a statically vs dynamically linked program

- On Ubuntu 16.04 (gcc 5.4.0, libc 2.23)
  - Statically linked trivial example
    - `gcc -m32 -static hello-int.c -o test`
    - 725KB
  - Dyncamically linked trivial example
    - `gcc -m32 hello-int.c -o test`
    - 7KB

Position independent code

(Parts adapted from Eli Bendersky)

https://eli.thegreenplace.net/2011/11/03/position-independent-code-pic-in-shared-libraries/

Position independent code

- Motivation
  - Share code of a library across all processes
    - E.g. libc is linked by all processes in the system
  - Code section should remain identical
    - To be shared read-only
  - What if library is loaded at different addresses?
    - Remember it needs to be relocated

Position independent code (PIC)

- Main idea:
  - Generate code in such a way that it can work no matter where it is located in the address space
  - Share code across all address spaces

What needs to be changed?

- Can stay untouched
  - Local jumps and calls are relative
  - Stack data is relative to the stack
- Needs to be modified
  - Global variables
  - Imported functions

Example

```
000010a4 <_main>:
    10a4: 55              pushl %ebp
    10a5: 89 e5           movl %esp,%ebp
    10a7: 68 10 00 00 00 pushl $0x10
      10a8: 32 .data
    10ac: e8 03 00 00 00 call 10b4 <_a>
  ...
000010b4 <_a>:
    10bc: e8 37 00 00 00 call 10f8 <_strlen>
     ...
    10c3: 6a 01 pushl $0x1
    10c5: e8 a2 00 00 00 call 116c <_write>
    ...
```

- Reference to a data section
  - Code and data sections can be moved around

Example

```
000010a4 <_main>:
    10a4: 55              pushl %ebp
    10a5: 89 e5           movl %esp,%ebp
    10a7: 68 10 00 00 00 pushl $0x10
      10a8: 32 .data
    10ac: e8 03 00 00 00 call 10b4 <_a>
  ...
000010b4 <_a>:
    10bc: e8 37 00 00 00 call 10f8 <_strlen>
     ...
    10c3: 6a 01 pushl $0x1
    10c5: e8 a2 00 00 00 call 116c <_write>
    ...
```

- Local function invocations use relative addresses
  - No need to relocate

Position independent code

- How would you build it?

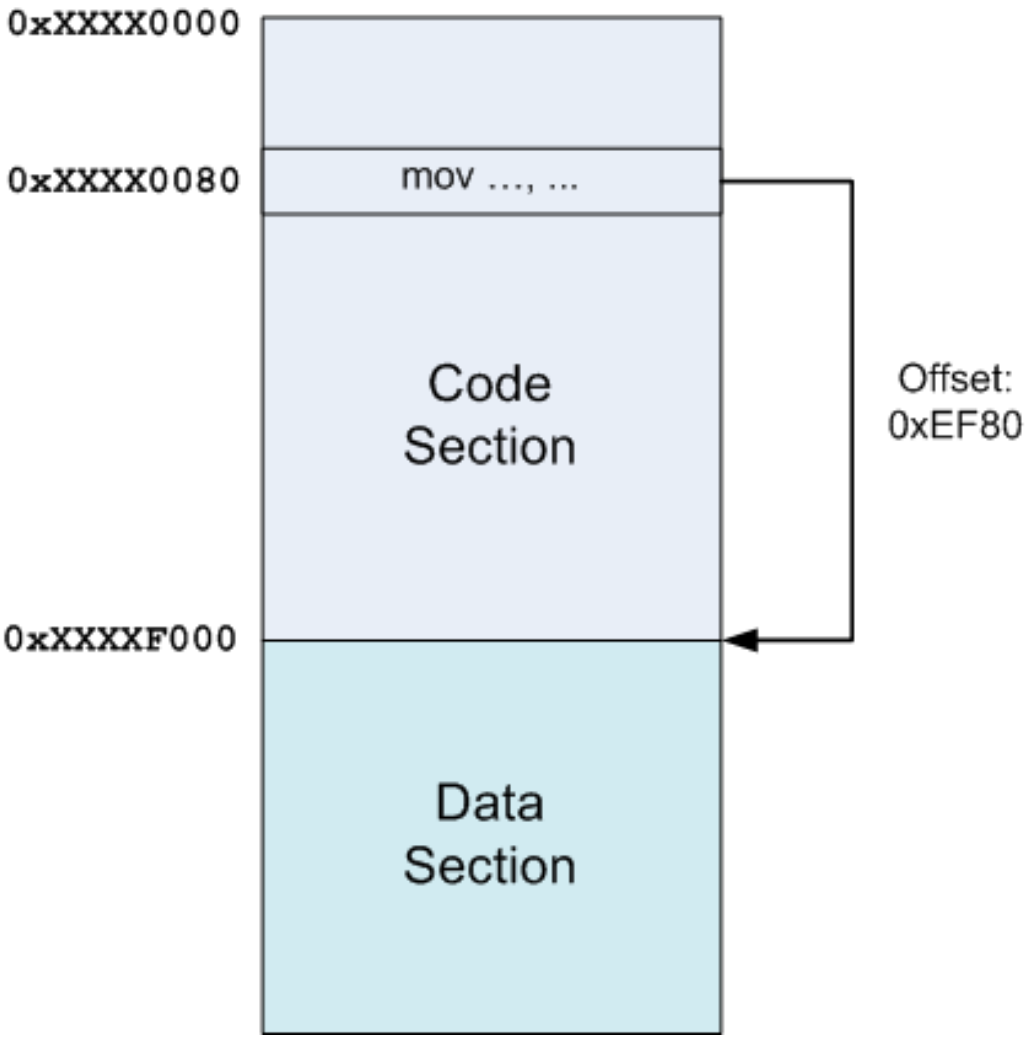
Position independent code

- How would you build it?
- Main idea:
  - Add additional layer of indirection to all
    - Global data
    - Function
    - ...references in the code

Position independent code

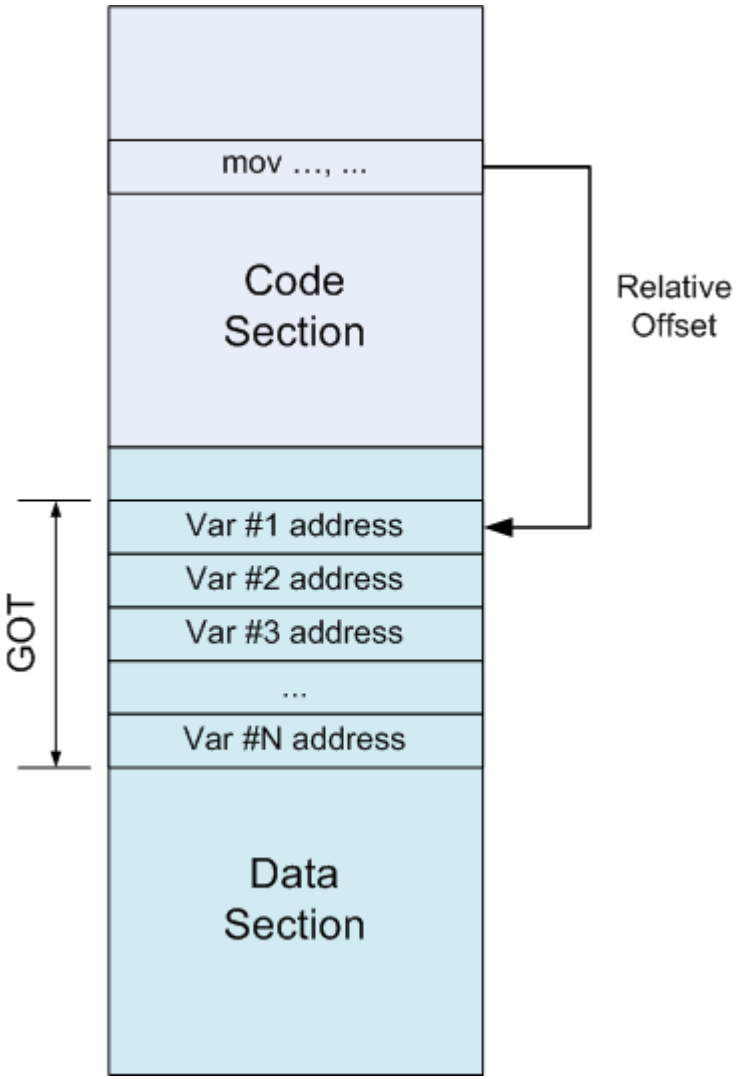
- Main insight
  - Code sections are followed by data sections
  - The distance between code and data **remains constant even if code is relocated**
    - Linker knows the distance
    - Even if it combines multiple code sections together

Insight 1: Constant offset between text and data sections



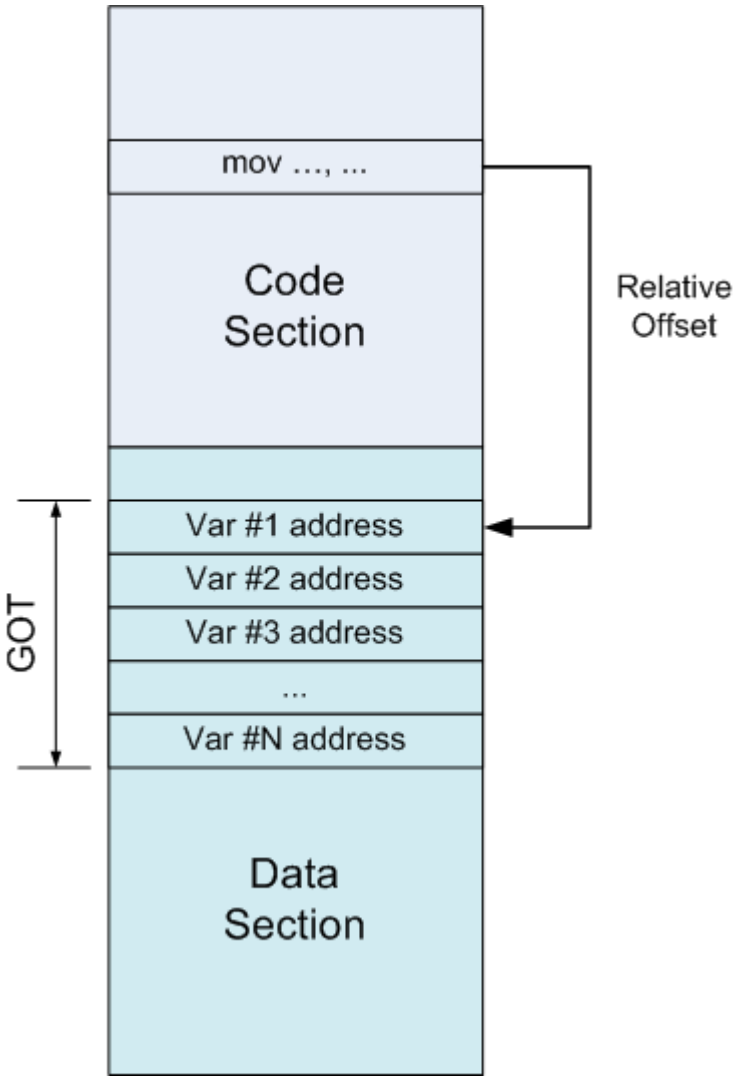
Global offset table (GOT)

- Insight #2:
  - Instead of referring to a variable by its absolute address
    - Which would require a relocation
  - Refer through GOT



Global offset table (GOT)

- GOT
  - Table of addresses
  - Each entry contains absolute address of a variable
  - GOT is patched by the linker at relocation time



How to find position of the code in memory at run time?

How to find position of the code in memory at run time?

- Is there an x86 instruction that does this?
  - i.e., give me my current code address

- x86 32bit architecture requires absolute addresses for `mov` instructions
  - No relative addresses allowed
- There is no instruction to learn the value of EIP
  - Instruction pointer

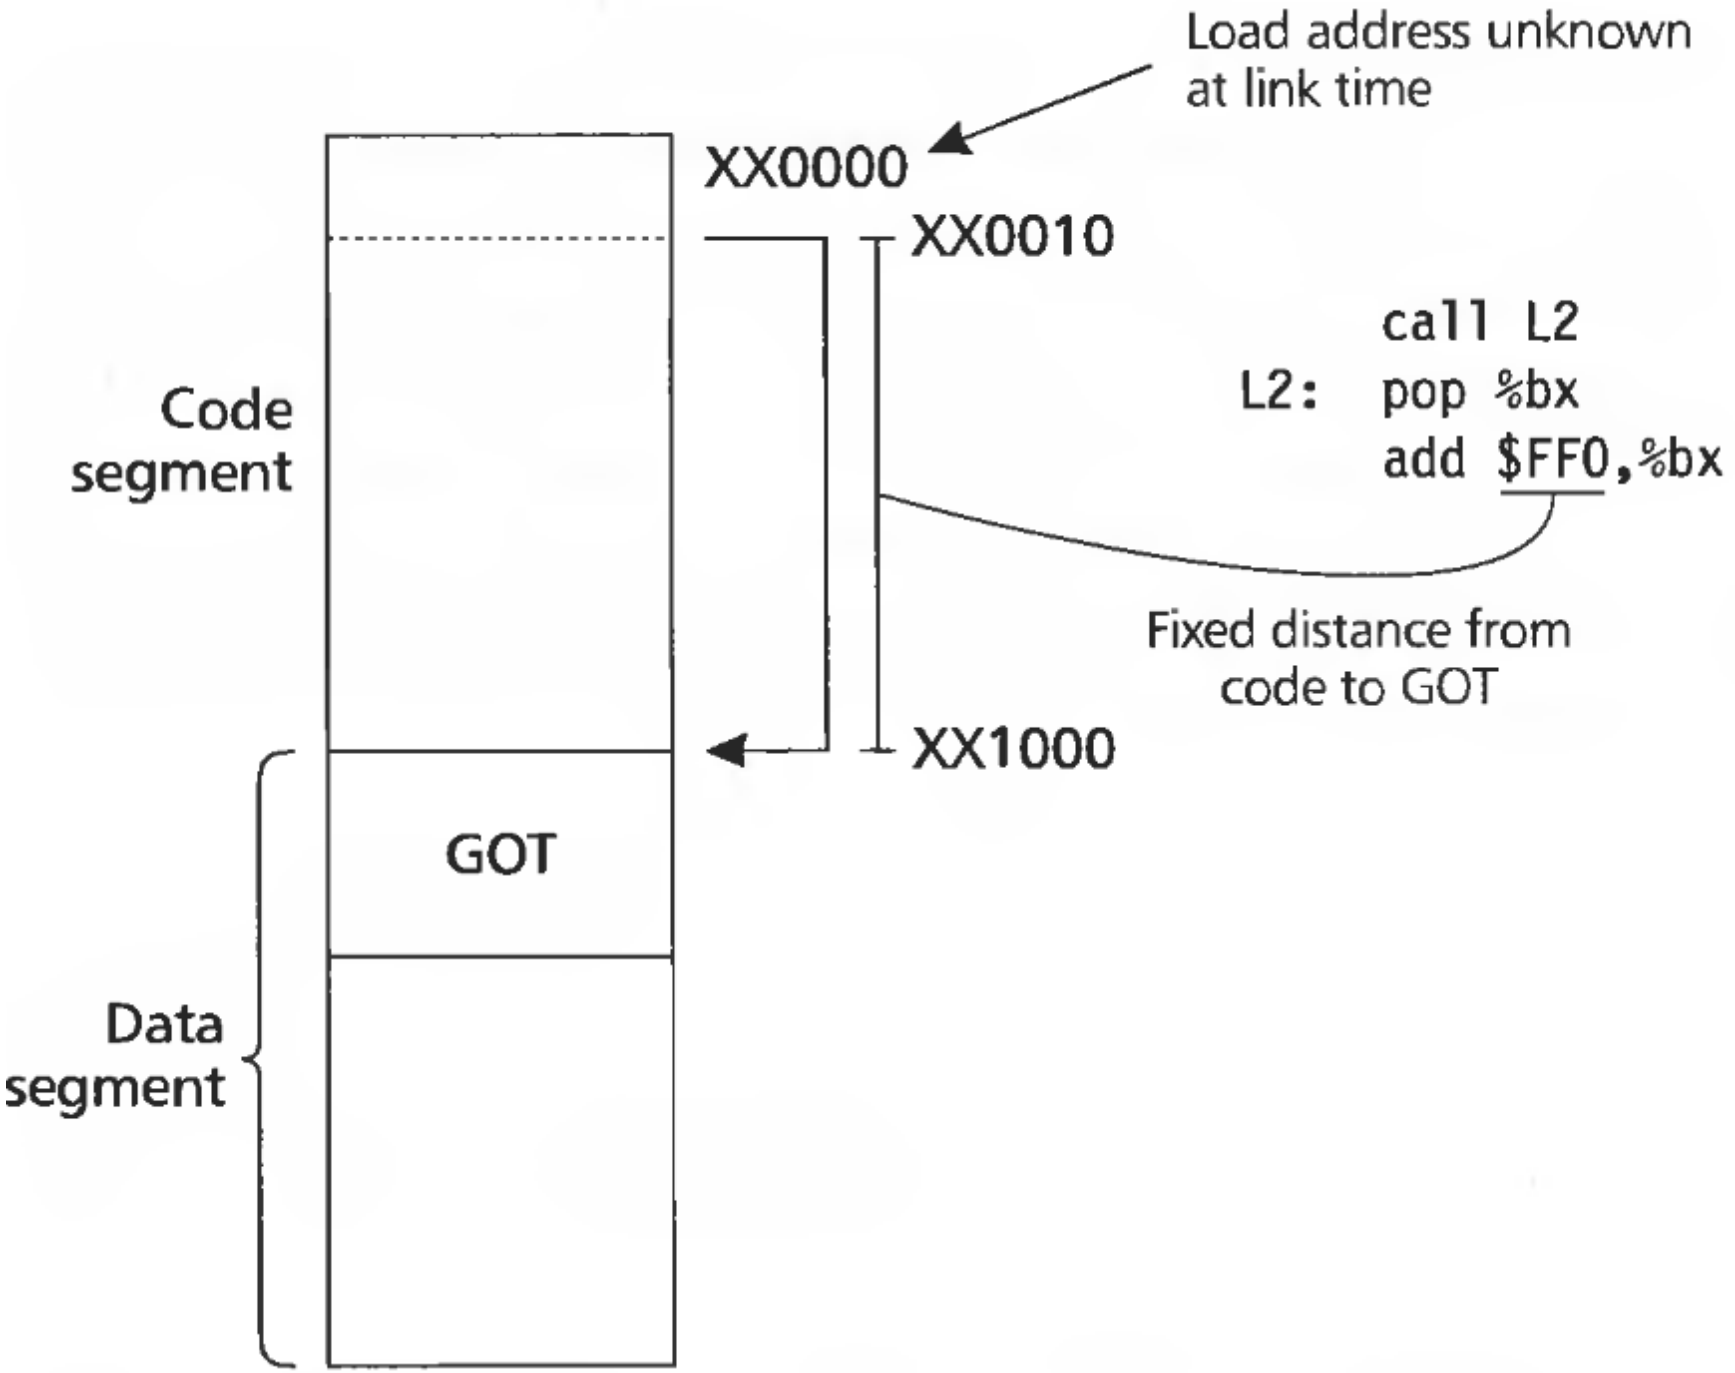
How to find position of the code in memory at run time?

- Simple trick

```
      call L2

L2: popl %ebx
```

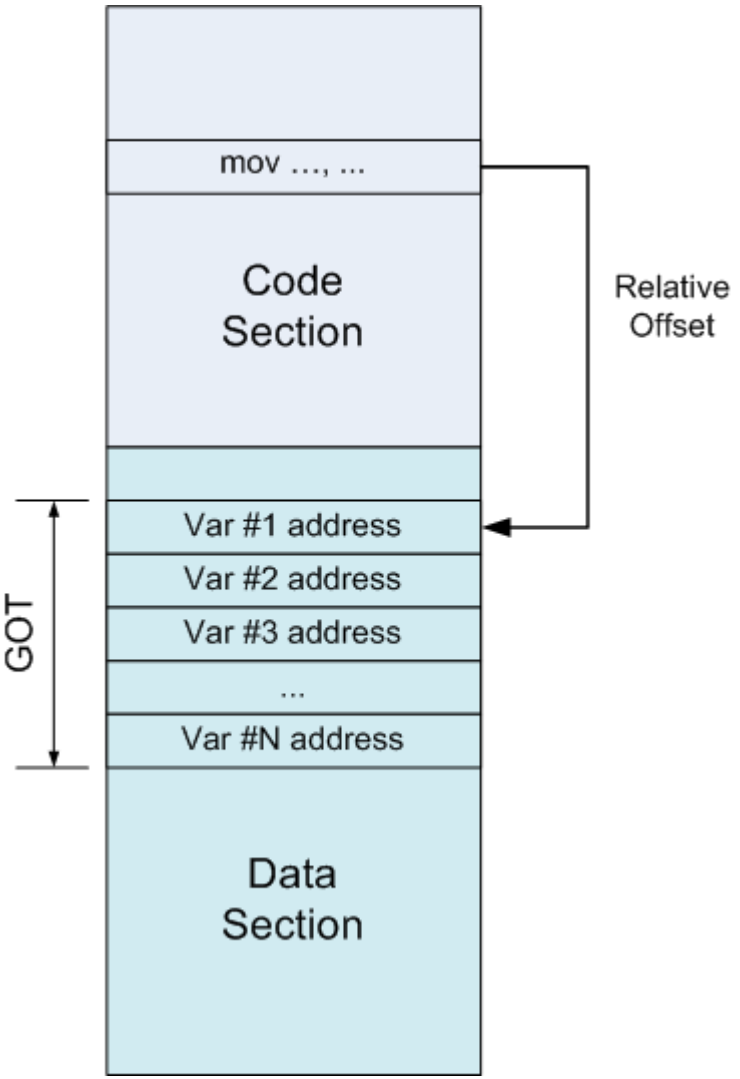
- Call next instruction
  - Saves EIP on the stack
  - EIP holds current position of the code
  - Use popl to fetch EIP into a register



Load address unknown
at link time
XX0000
XX0010
call L2
L2: pop %bx
add $FF0,%bx
Code
segment
Fixed distance from
code to GOT
XX1000
GOT
Data
segment

What did we gain?

- Processes can share code
- Each have private GOT
- Why is it better?
  - GOT is in the data section, private to each process anyway
    - We saved memory
  - We saved some linking time too
    - GOT is patched per variable, not per variable reference
    - There are many references to the same variable in the code
    - It takes some time to relocate
    - We saved this time



PIC: Advantages and disadvantages

- Any ideas?

PIC: Advantages and disadvantages

- Bad
  - Code gets slower
    - One register is wasted to keep GOT pointer
      - x86 has 6 registers, loosing one of them is bad
    - One more memory dereference
      - GOT can be large (lots of global variables)
      - Extra memory dereferences can have a high cost due to cache misses
    - One more call to find GOT
- Good
  - Share memory of common libraries
  - Address space randomization

Thank you!

PIC example

```
int myglob = 42;

int ml_func(int a, int b)
{
    return myglob + a + b;
}
```

```
0000043c <ml_func>:
 43c:   55                      push   ebp
 43d:   89 e5                   mov    ebp,esp
 43f:   e8 16 00 00 00          call   45a <__i686.get_pc_thunk.cx>
 444:   81 c1 b0 1b 00 00       add    ecx,0x1bb0
 44a:   8b 81 f0 ff ff ff       mov    eax,DWORD PTR [ecx-0x10]
 450:   8b 00                   mov    eax,DWORD PTR [eax]
 452:   03 45 08                add    eax,DWORD PTR [ebp+0x8]
 455:   03 45 0c                add    eax,DWORD PTR [ebp+0xc]
 458:   5d                      pop    ebp
 459:   c3                      ret

0000045a <__i686.get_pc_thunk.cx>:
 45a:   8b 0c 24                mov    ecx,DWORD PTR [esp]
 45d:   c3                      ret
```

PIC example

```
int myglob = 42;

int ml_func(int a, int b)
{
    return myglob + a + b;
}
```

- Access a global variable

```
0000043c <ml_func>:
 43c:   55                      push   ebp
 43d:   89 e5                   mov    ebp,esp
 43f:   e8 16 00 00 00          call   45a <__i686.get_pc_thunk.cx>
 444:   81 c1 b0 1b 00 00       add    ecx,0x1bb0
 44a:   8b 81 f0 ff ff ff       mov    eax,DWORD PTR [ecx-0x10]
 450:   8b 00                   mov    eax,DWORD PTR [eax]
 452:   03 45 08                add    eax,DWORD PTR [ebp+0x8]
 455:   03 45 0c                add    eax,DWORD PTR [ebp+0xc]
 458:   5d                      pop    ebp
 459:   c3                      ret

0000045a <__i686.get_pc_thunk.cx>:
 45a:   8b 0c 24                mov    ecx,DWORD PTR [esp]
 45d:   c3                      ret
```

PIC example

- Save EIP into ECX

```
int myglob = 42;

int ml_func(int a, int b)
{
    return myglob + a + b;
}
```

```
0000043c <ml_func>:
 43c:   55                      push   ebp
 43d:   89 e5                   mov    ebp,esp
 43f:   e8 16 00 00 00          call   45a <__i686.get_pc_thunk.cx>
 444:   81 c1 b0 1b 00 00       add    ecx,0x1bb0
 44a:   8b 81 f0 ff ff ff       mov    eax,DWORD PTR [ecx-0x10]
 450:   8b 00                   mov    eax,DWORD PTR [eax]
 452:   03 45 08                add    eax,DWORD PTR [ebp+0x8]
 455:   03 45 0c                add    eax,DWORD PTR [ebp+0xc]
 458:   5d                      pop    ebp
 459:   c3                      ret

0000045a <__i686.get_pc_thunk.cx>:
 45a:   8b 0c 24                mov    ecx,DWORD PTR [esp]
 45d:   c3                      ret
```

PIC example

```
int myglob = 42;

int ml_func(int a, int b)
{
    return myglob + a + b;
}
```

- Add offset to GOT
  - 0x1bb0

```
0000043c <ml_func>:
 43c:   55                      push   ebp
 43d:   89 e5                   mov    ebp,esp
 43f:   e8 16 00 00 00          call   45a <__i686.get_pc_thunk.cx>
 444:   81 c1 b0 1b 00 00       add    ecx,0x1bb0
 44a:   8b 81 f0 ff ff ff       mov    eax,DWORD PTR [ecx-0x10]
 450:   8b 00                   mov    eax,DWORD PTR [eax]
 452:   03 45 08                add    eax,DWORD PTR [ebp+0x8]
 455:   03 45 0c                add    eax,DWORD PTR [ebp+0xc]
 458:   5d                      pop    ebp
 459:   c3                      ret

0000045a <__i686.get_pc_thunk.cx>:
 45a:   8b 0c 24                mov    ecx,DWORD PTR [esp]
 45d:   c3                      ret
```

PIC example

```
int myglob = 42;

int ml_func(int a, int b)
{
    return myglob + a + b;
}
```

- Access address of a specific GOT entry
  - Save it in EAX

```
0000043c <ml_func>:
 43c:   55                      push   ebp
 43d:   89 e5                   mov    ebp,esp
 43f:   e8 16 00 00 00          call   45a <__i686.get_pc_thunk.cx>
 444:   81 c1 b0 1b 00 00       add    ecx,0x1bb0
 44a:   8b 81 f0 ff ff ff       mov    eax,DWORD PTR [ecx-0x10]
 450:   8b 00                   mov    eax,DWORD PTR [eax]
 452:   03 45 08                add    eax,DWORD PTR [ebp+0x8]
 455:   03 45 0c                add    eax,DWORD PTR [ebp+0xc]
 458:   5d                      pop    ebp
 459:   c3                      ret

0000045a <__i686.get_pc_thunk.cx>:
 45a:   8b 0c 24                mov    ecx,DWORD PTR [esp]
 45d:   c3                      ret
```

PIC example

```
int myglob = 42;

int ml_func(int a, int b)
{
    return myglob + a + b;
}
```

- Load the value of the variable at the address pointed by EAX
  - In EAX again

```
0000043c <ml_func>:
 43c:   55                      push   ebp
 43d:   89 e5                   mov    ebp,esp
 43f:   e8 16 00 00 00          call   45a <__i686.get_pc_thunk.cx>
 444:   81 c1 b0 1b 00 00       add    ecx,0x1bb0
 44a:   8b 81 f0 ff ff ff       mov    eax,DWORD PTR [ecx-0x10]
 450:   8b 00                   mov    eax,DWORD PTR [eax]
 452:   03 45 08                add    eax,DWORD PTR [ebp+0x8]
 455:   03 45 0c                add    eax,DWORD PTR [ebp+0xc]
 458:   5d                      pop    ebp
 459:   c3                      ret

0000045a <__i686.get_pc_thunk.cx>:
 45a:   8b 0c 24                mov    ecx,DWORD PTR [esp]
 45d:   c3                      ret
```

What about function calls?

What about function calls?

- Same approach can work
- But this is not how it is done

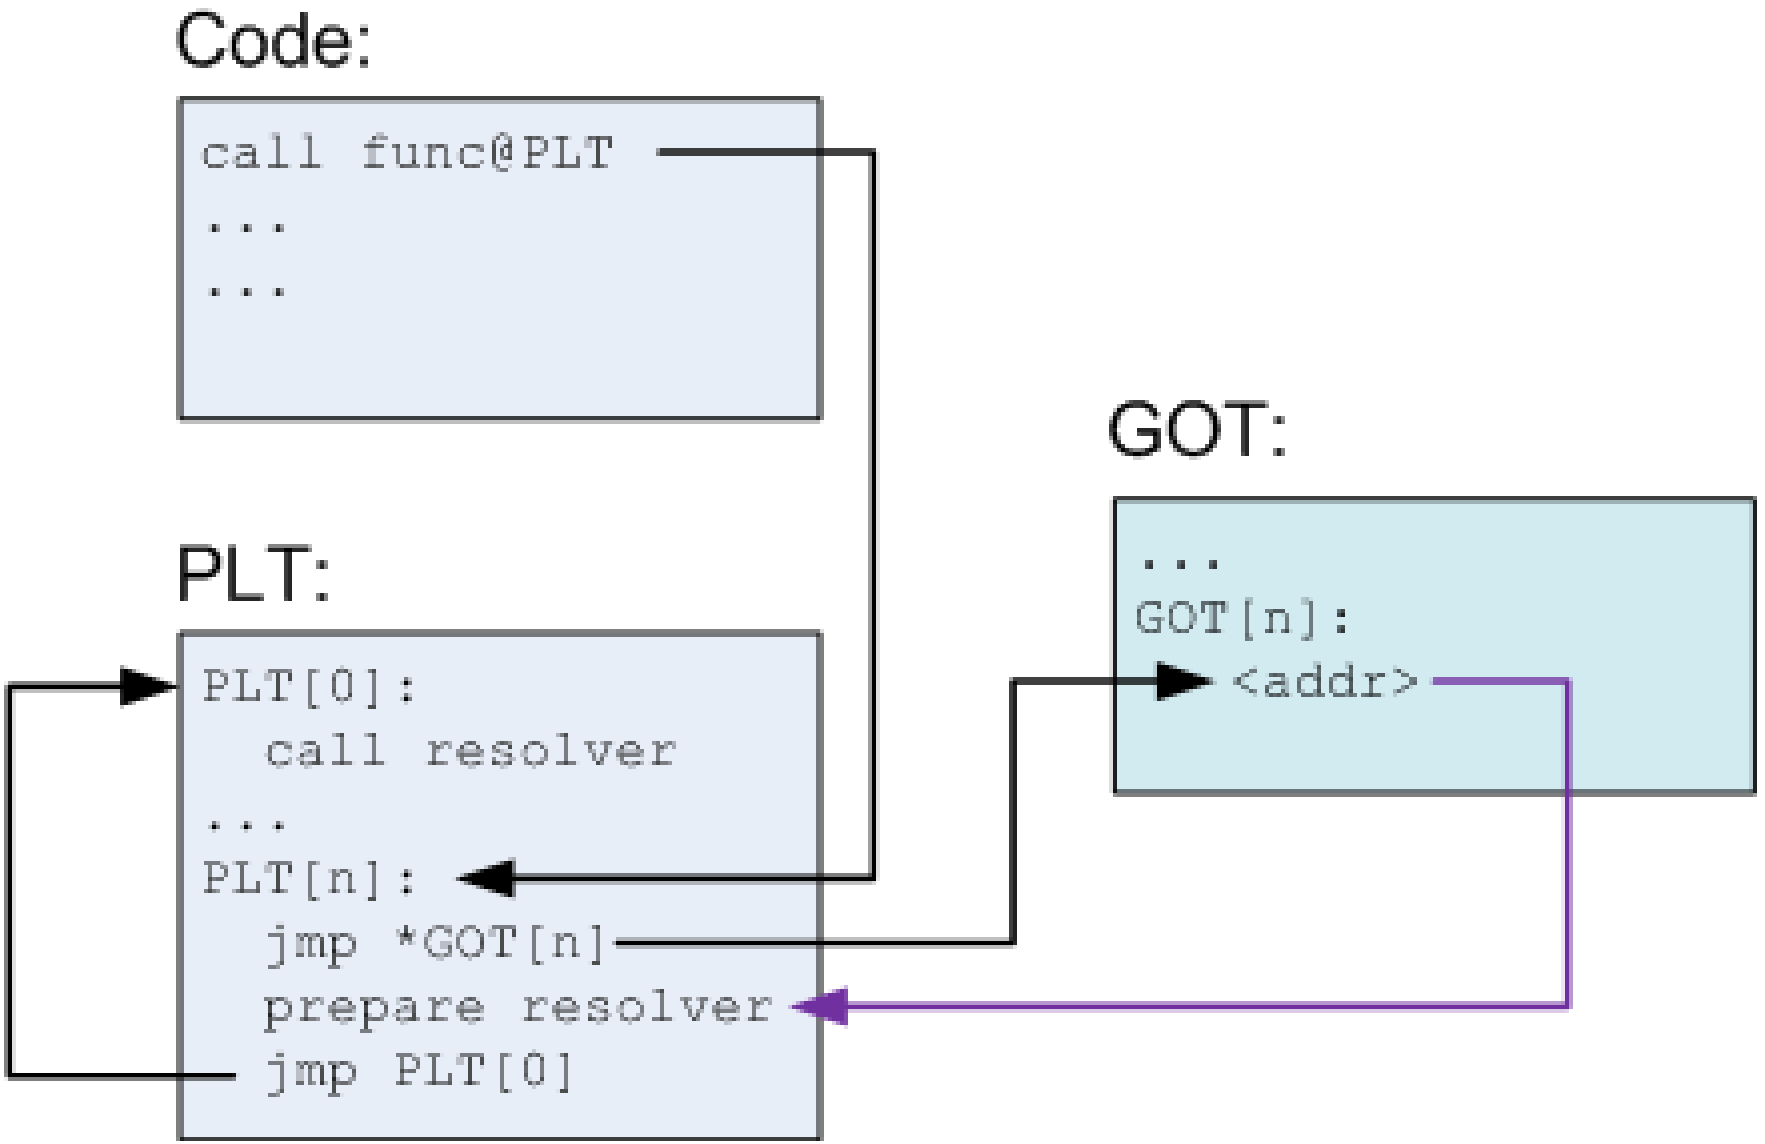
Late binding

- When a shared library refers to some function, the real address of that function is not known until load time
  - Resolving this address is called binding
- We can use GOT
  - Same as for variables

Lazy procedure binding

- In large libraries many routines are never called
  - Libc has over 600
    - **The number of functions is much larger than the number of global variables**
  - It's ok to bind all routines when the program is statically linked
    - Binding is done offline, no runtime costst
  - But with dynamic linking run-time overhead is too high
    - **Lazy approach, i.e., linking only when used, works better**

Procedure linkage table (PLT)



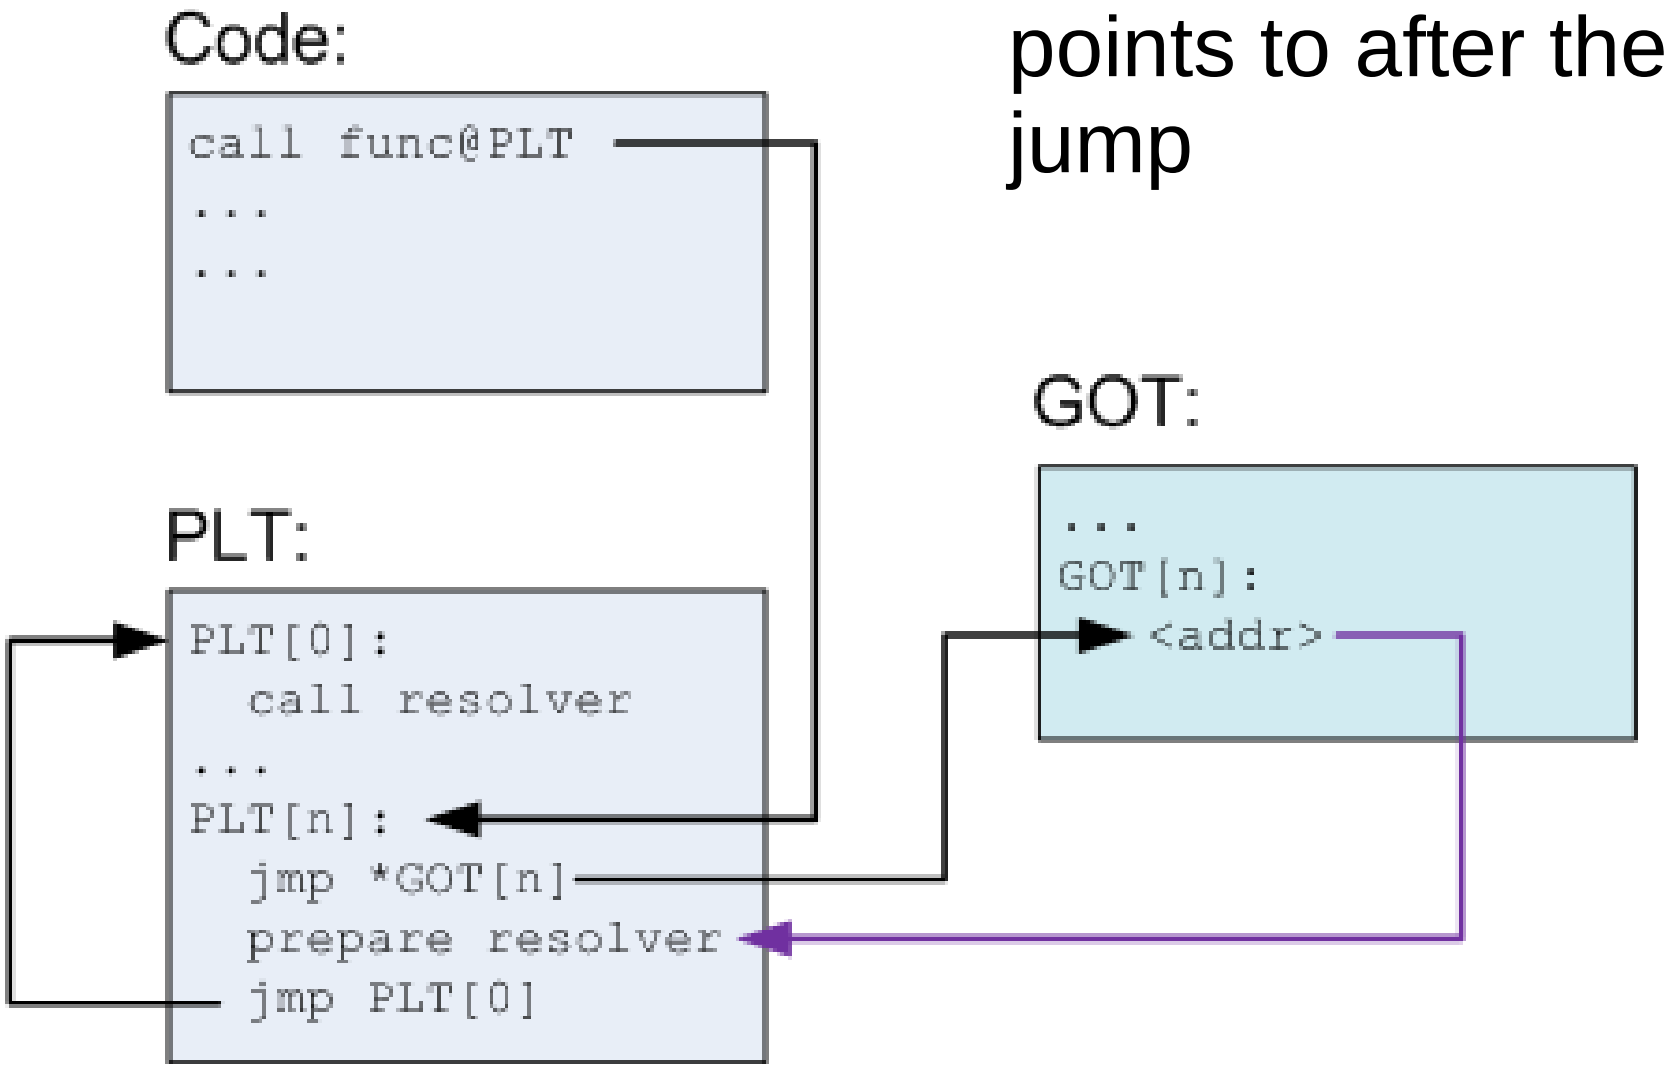
Procedure linkage table (PLT)

- PLT is part of the executable text section
  - A set of entries
    - A special first entry
    - One for each external function
- Each PLT entry
  - Is a short chunk of executable code
  - Has a corresponding entry in the GOT
    - Contains an actual offset to the function
    - Only after it is resolved by the dynamic loader

- Each PLT entry but the first consists of these parts:
  - A jump to a location which is specified in a corresponding GOT entry
  - Preparation of arguments for a "resolver" routine
  - Call to the resolver routine, which resides in the first entry of the PLT

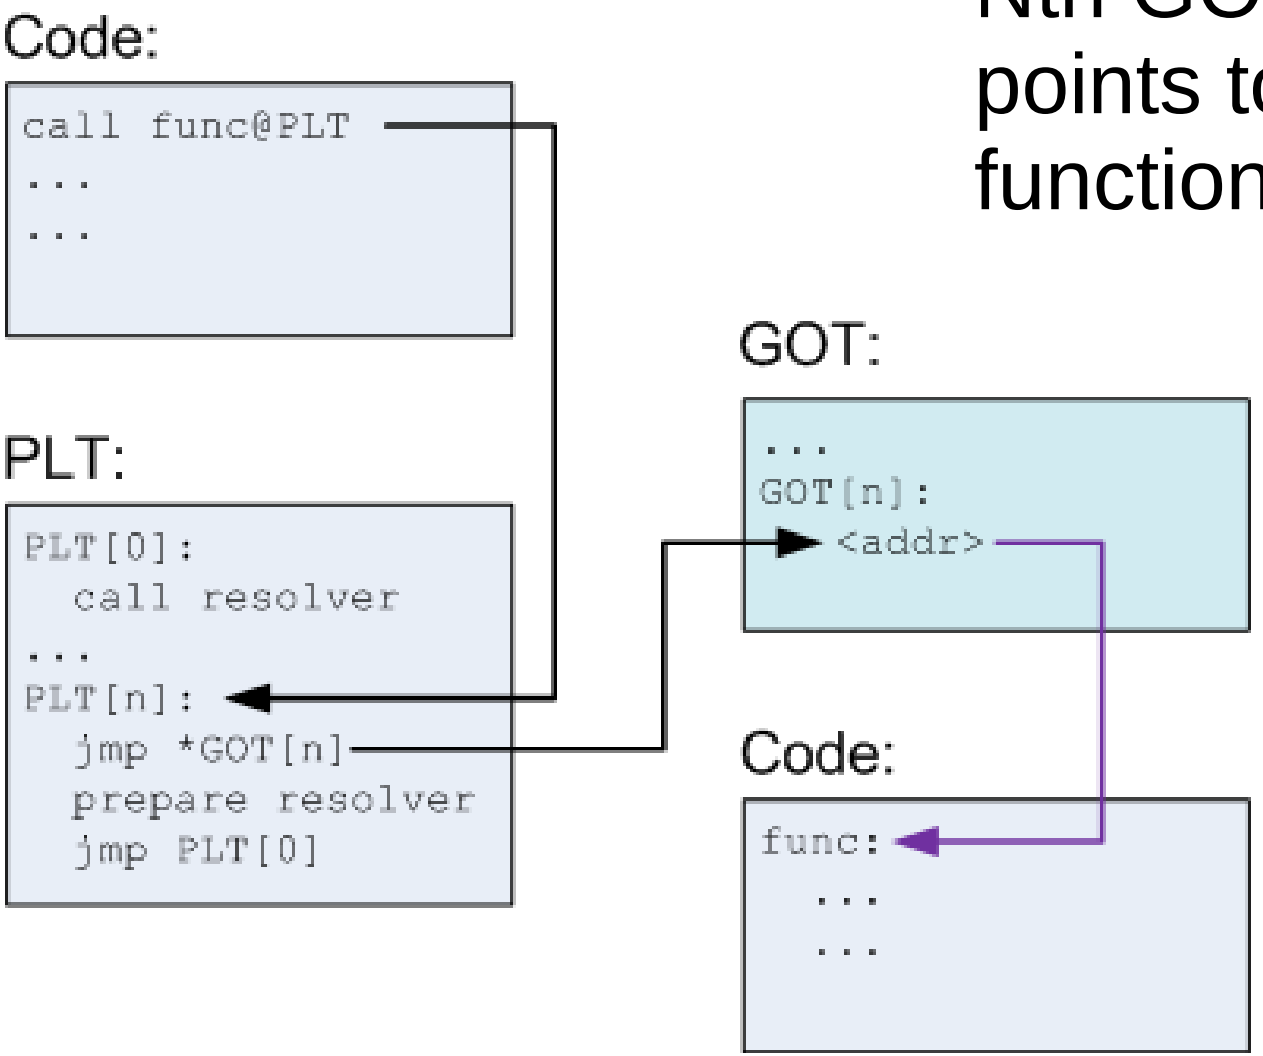
Before function is resolved

- Nth GOT entry points to after the jump



PLT after the function is resolved

- Nth GOT entry points to the actual function



PIC example (functions)

```
int ml_util_func(int a)
{
    return a + 1;
}
int ml_func(int a, int b)
{
    int c = b + ml_util_func(a);
    myglob += c;
    return b + myglob;
}
```

```
00000477 <ml_func>:
 477:   55                      push   ebp
 478:   89 e5                   mov    ebp,esp
 47a:   53                      push   ebx
 47b:   83 ec 24                sub    esp,0x24
 47e:   e8 e4 ff ff ff          call   467 <__i686.get_pc_thunk.bx>
 483:   81 c3 71 1b 00 00       add    ebx,0x1b71
 489:   8b 45 08                mov    eax,DWORD PTR [ebp+0x8]
 48c:   89 04 24                mov    DWORD PTR [esp],eax
 48f:   e8 0c ff ff ff          call   3a0 <ml_util_func@plt>
 ...

000003a0 <ml_util_func@plt>:
 3a0:   ff a3 14 00 00 00       jmp    DWORD PTR [ebx+0x14]
 3a6:   68 10 00 00 00          push   0x10
 3ab:   e9 c0 ff ff ff          jmp    370 <_init+0x30>
```

PIC example (functions)

```
int ml_util_func(int a)
{
    return a + 1;
}
int ml_func(int a, int b)
{
    int c = b + ml_util_func(a);
    myglob += c;
    return b + myglob;
}
```

- Resolve the address of GOT
- First learn EIP
  - Saved in EBX
- Then add offset to EBX

```
00000477 <ml_func>:
 477:   55                      push   ebp
 478:   89 e5                   mov    ebp,esp
 47a:   53                      push   ebx
 47b:   83 ec 24                sub    esp,0x24
 47e:   e8 e4 ff ff ff          call   467 <__i686.get_pc_thunk.bx>
 483:   81 c3 71 1b 00 00       add    ebx,0x1b71
 489:   8b 45 08                mov    eax,DWORD PTR [ebp+0x8]
 48c:   89 04 24                mov    DWORD PTR [esp],eax
 48f:   e8 0c ff ff ff          call   3a0 <ml_util_func@plt>
 ...

000003a0 <ml_util_func@plt>:
 3a0:   ff a3 14 00 00 00       jmp    DWORD PTR [ebx+0x14]
 3a6:   68 10 00 00 00          push   0x10
 3ab:   e9 c0 ff ff ff          jmp    370 <_init+0x30>
```

PIC example (functions)

```
int ml_util_func(int a)
{
    return a + 1;
}
int ml_func(int a, int b)
{
    int c = b + ml_util_func(a);
    myglob += c;
    return b + myglob;
}
```

```
00000477 <ml_func>:
 477:   55                      push   ebp
 478:   89 e5                   mov    ebp,esp
 47a:   53                      push   ebx
 47b:   83 ec 24                sub    esp,0x24
 47e:   e8 e4 ff ff ff          call   467 <__i686.get_pc_thunk.bx>
 483:   81 c3 71 1b 00 00       add    ebx,0x1b71
 489:   8b 45 08                mov    eax,DWORD PTR [ebp+0x8]
 48c:   89 04 24                mov    DWORD PTR [esp],eax
 48f:   e8 0c ff ff ff          call   3a0 <ml_util_func@plt>
 ...
```

```
000003a0 <ml_util_func@plt>:
 3a0:   ff a3 14 00 00 00       jmp    DWORD PTR [ebx+0x14]
 3a6:   68 10 00 00 00          push   0x10
 3ab:   e9 c0 ff ff ff          jmp    370 <_init+0x30>
```

- Jump to an address specified in GOT
  - This is the jump to [ebx+0x14]
- Prepare arguments for the resolver
- Call resolver

Back to shared libraries

Loading a dynamically linked ELF program

- Map ELF sections into memory
- Note the interpreter section
  - Usually ld.so
- Map ld.so into memory
  - Start ld.so instead of the program
- Linker (ld.so) intializes itself
- Finds the names of shared libraries required by the program
  - DT_NEEDED entries

Finding libraries in the file system

- DT_RPATH symbol
  - Can be linked into a file by a normal linker at link time
- LD_LIBRARY_PATH
- Library cache file
  - /etc/ld.so.conf
  - This is the most normal way to resolve library paths
- Default library path
  - /usr/lib

Loading more libraries

- When the library is found it is loaded into memory
  - Linker adds its symbol table to the linked list of symbol tables
  - Recursively searches if the library depends on other libraries
    - Loads them if needed

Shared library initialization

- Remember PIC needs relocation in the data segment and GOT
  - ld.so linker performs this relocation

Conclusion

- Program loading
  - Storage allocation
- Relocation
  - Assign load address to each object file
  - Patch the code
- Symbol resolution
  - Resolve symbols imported from other object files

Weak vs strong symbols

- Virtually every program uses printf
  - Printf can convert floating-point numbers to strings
    - Printf uses fcvt()
  - Does this mean that every program needs to link against floating-point libraries?
- Weak symbols allow symbols to be undefined
  - If program uses floating numbers, it links against the floating-point libraries
    - fcvt() is defined an everything is fine
  - If program doesn't use floating-point libraries
    - fcvt() remains NULL but is never called

```
1. #include <stdio.h>
2.
3. void func_a(void){
4.     printf("func_a\n");
5.     return;
6. }
7.
8. void func_b(void) {
9.     printf("func_b\n");
10.     return;
11. }
12.
13. int main(int ac, char **av)
14. {
15.    void (*fp)(void);
16.
17.    fp = func_b;
18.    fp();
19.    return;
20. }
```

Function pointers

```
